CRITICISM OF THE HEALTH ASSESSMENT IN THE ICNIRP GUIDELINES FOR RADIOFREQUENCY AND MICROWAVE RADIATION (100 kHz - 300 GHz)

**Neil Cherry
Lincoln University
31/1/2000**

Abstract:

Dr Cherry was invited by the Ministry of Health/ Ministry for the Environment of New Zealand to carry out a peer-review of the proposal to adopt the ICNIRP guidelines for cell sites in New Zealand, in November 1999. The ICNIRP guidelines were covered by a published assessment in 1998. This review shows that the assessment had ignored all published studies showing chromosome damage. It was highly selective, biased and very dismissive of the genotoxic evidence and the epidemiological evidence of cancer effects and reproductive effects. The assessment gives the strong impression of being predetermined in the belief that the only effects were from high exposures that cause electric shocks and acute exposures that cause tissue heating. For, example, they cite two studies saying that they do not show any significant increased effects of Brain/CNS cancer from microwave exposures when the actual published papers, Grayson (1996) and Beall et al. (1996), both do show significant increases of Brain/CNS cancer.

1. INTRODUCTION:

1.1 Background to this critique

There is a strong push from the WHO and the ICNIRP of harmonize national RF/MW exposure standards by individual states adopting the ICNIRP Guideline. This would be a good thing if the ICNIRP Guideline was set at an exposure level that provided sound protection of public health. The evidence presented here shows that the ICNIRP Guideline exposure level is set many orders of magnitude too high to accomplish this. It is based on the preconceived and long held view of Western Government Authorities that the only possible and only established biological effect of RF/MW exposure is tissue heating. This is referred to here as the RF-Thermal View. This view has been intransigently maintained in the face of compelling laboratory and epidemiological evidence of adverse health effects that would have had a chemical declared carcinogenic, neuropathogenic, cardiogenic and teratogenic for humans many years ago.

This critique was originally written when the New Zealand Ministries of Health and Environment proposed to adopt the ICNIRP Guideline as the Public Health Standard for Cell Site exposures. At the same time the New Zealand RF Standards Committee was proposing to use the ICNIRP Guideline as the New Zealand RF/MW Standard. ICNIRP is the International Commission on Non-Ionizing Radiation Protection. The ICNIRP RF/MW guideline and scientific assessment was published in Health Physics, Vol. 74 (4): 494-522, 1988. This is the primary source document for this critique and will be referred to as ICNIRP (1998).

The ICNIRP (1998) assessment of effects has been reviewed against the research literature cited and other published research. It is found that both the basic approach of ICNIRP and its treatment of the scientific research have serious flaws. The ICNIRP assessment is determined to maintain the RF-Thermal View and it rejects or omits all evidence that conflicts with this view. This may be termed "Constructive Dismissal" for a preconceived concept is used to inappropriately dismiss all evidence that challenges it.

ICNIRP is particularly dismissive of epidemiological evidence because all existing studies involve nonthermal exposures. Hence accepting the validity of these studies would directly challenge the RF-Thermal View. In this way the approach to dealing with health effects from non-ionizing radiation was developed to follow a completely different method than for toxic chemicals, drugs or air pollution. Both the approach of ICNIRP and the assumptions made are severely scientifically challenged in this report.

1.2 Overview of this report:

Public health protection standards for toxic substances, chemicals, drugs, air pollution, ionizing radiation are set by WHO, IARC, E.U., U.S. EPA and the U.K. Royal Commission on Environmental Pollution primarily using epidemiological evidence and secondarily using animal evidence. WHO and ICNIRP base non-ionizing radiation protection standards on a single biological mechanism, Tissue Heating. They systematically reject or ignore all epidemiological and animal evidence of non-thermal effects, for which there is a large body.

The history and basis of the RF-Thermal View which dominates ICNIRP, WHO, and national authority approaches, is documented and summarized. It will be shown that throughout the post-War period scientific research and leading biological and medical scientists have challenged the RF-thermal assumptions. They present very strong evidence, amounting to proof, that biological systems intrinsically use EMR for body, organ, hormone and cellular functions and regulation, and that extrinsic EMR interferes with these at extremely low exposure levels. These biological effects do not involve heat but do involve non-linear, non-equilibrium resonant interactions between ELF oscillating signals.

The well documented and established nonthermal biological effects of EMR include significant alteration of cellular calcium ion homeostasis, reduction of melatonin and the detection of Schumann Resonances by human and avian brains, DNA strand breakage and enhanced chromosome aberrations.

The human health implications of these biological effects are discussed and documented. This shows that calcium ion efflux/influx and melatonin reduction are separately and jointly linked to DNA strand breaks, chromosome aberrations, enhanced proto oncogene activity, impaired immune system competence and impaired neurological and cardiac functioning. Many projects, from independent laboratories, have observed and reported that all of these effects are significantly related to EMR exposure.

Human Biometeorology is a whole body of research that is ignored by ICNIRP. This has provided the proof over 30 years ago that human brains detect and use the Schumann Resonances for synchronization of biological rhythms, i.e. as a Zeitgeber. This observation on its own is an absolute challenge to the validity of the ICNIRP assumptions that there are no established non-thermal biological effects.

Epidemiological reviews by Dr John Goldsmith show that adverse health effects, such as neurological, reproductive and cancer effects have been observed in EMR exposed populations. Based on this, and the traditional public health protection approach, Dr Goldsmith challenges the validity of the ICNIRP guideline and approach.

To summarize the scientific evidence an initial set of eight bioelectromagnetic principles are proposed and a brief summary of the scientific research that supports them is given. They are:

- EMR is intrinsic to our bodies.
- Our brains are the most electrically sensitive organs in our bodies.
- Our hearts are electrically sensitive.
- Cells are sensitive to EMR
- Our whole body acts as an aerial
- The brain is linked to organs and cells through EMR-sensitive hormones.
- The EMR Spectrum Principle.
- The Intrinsic Free Radical Principle

These principles provide a sound and scientifically reliable approach to assessing EMR impacts on people and animals. They soundly challenge the ICNIRP assumptions and approach. The ICNIRP assessment of biological mechanisms is reviewed and found to be selective, limited and flawed. Their assessment of RF/MW effects on reproductive outcomes is shown to be limited, misleading and flawed. The cancer assessment is shown to be selective, misleading, inappropriate and flawed. An incorrect epidemiological approach is consistently applied.

From the data in the studies cited (and misused) by the ICNIRP and WHO reviews, and supported by a great deal of other available research evidence, a public health protection standard is recommended based on residential dose-response relationships for cancer, neurological effects and reproductive effects.

2. Public Health Protection Standards are based on Epidemiology:

The background to identifying environmental factors which produce cancer will be given, along with an example using the chemical Benzene. Then the principles of epidemiology relating to assessment of cause and effect will be outlined and the particular principles in the epidemiology of EMR will be discussed.

2.1 Cancer Assessments are based on environmental epidemiology:

Public health Protection Standards are based on Epidemiological Evidence. A primary textbook on Cancer De Vita, Hellman and Rosenberg (1993), states:

"In contrast to laboratory studies, epidemiology directly evaluates the experience of human populations and their response to various environmental exposures and host factors (the risk of disease)".

Regato, Spjut and Cox (1985) introduce their medical textbook on cancer by discussing the use of Incidence Rates in human populations as the means of detecting human cancers. Fraumeni et al. (1993) outline the historical role that epidemiology has played in identifying carcinogenic agents and the range of methods which are classically used.

Setting public health standards for environmental carcinogens is the role of the United States Environmental Protection Agency (USEPA). Their website includes the Integrated Risk Information System (IRIS), <http://www.epa.gov/ngispgm3/iris/rfd.htm>, that details the procedures for carrying out assessments and the results for a wide range of carcinogens. This is primarily based on epidemiological assessments. Under the heading "Hazard Identification" the following statement relates to the use of epidemiological studies:

"Human data are often useful in quantitatively establishing the presence of an adverse effect in exposed human populations. When there is information on the exposure level associated with an appropriate endpoint, epidemiologic studies can also provide the basis for a quantitative dose-response assessment. The presence of such data obviates the necessity of extrapolating from animals to humans; therefore, human studies, when available, are given first priority, with animal studies serving to complement them."

An environmental epidemiologist of considerable standing, alongside Sir Austin Bradford Hill, was Professor Abraham Lilienfeld, of Johns Hopkins University. He was the epidemiologist responsible for the survey of health effects at the U.S. Embassy in Moscow. In his paper "Practical limitations of Epidemiologic methods" (Lilienfeld, 1983), Professor Abraham Lilienfeld discussed some of the difficulties of demographic studies, including the issue of the "ecological fallacy". In relation to his study on the staff and dependents at the U.S. Moscow Embassy, he states:

"The problems associated with these studies are illustrated by reviewing some of the details of the study of effects of microwave radiation on embassy employees in Moscow. The study population had to be reconstructed, individuals had to be located and information on exposure status has to be obtained by questionnaire. The relatively small size of the exposed group permitted the detection of only fairly large relative risks. Despite these limitations, epidemiologic studies have been remarkably productive in elucidating etiological factors. They are necessary since *'the proper study of man is man'* ".

Dr Lilienfeld describes a classical epidemiological approach and problems. Epidemiology is complex and difficult, but it is the best and most appropriate science for the study of the effects of environmental exposures on human populations.

2.2 A Chemical Example - Benzene:

An example is the carcinogenic assessment for Benzene. Benzene is classified as a known human carcinogen (Category A) based on "convincing human evidence as well as supporting evidence from animal studies". At the end of the section on "Human Carcinogenicity Data" the conclusion is:

"All of the epidemiological studies referred to above have some methodological problems, i.e. confounding exposures, lack of sufficient power, and other limitations, but the consistent excess risk of leukaemia across all of these studies argues that such problems could not be entirely responsible for the elevated risks of cancer. Most of these epidemiologic studies have been reviewed in peer-reviewed publications. They provide clear evidence of a causal association between exposure to Benzene and ANLL. The evidence is suggestive with respect to CNLL and CLL."

ANLL: Acute Nonlymphocytic Leukaemia.

CNLL: Chronic Nonlymphocytic Leukaemia.

CLL: Chronic Lymphocytic Leukaemia.

The Benzene Assessment is based on a total of 15 epidemiological papers covering 6 separate studies, one showing a significant dose-response relationship. Several papers found insignificantly elevated leukaemia rates. Some of these reached significance when follow-up studies involved more cases. In summary the dose-response data gives:

Table 1: Air concentrations at specific risk levels:

Risk Level	Concentration of Benzene
1 in 10,000	13.0 to 45.0 $\mu\text{g}/\text{m}^3$
1 in 100,000	1.3 to 4.5 $\mu\text{g}/\text{m}^3$
1 in 1,000,000	0.13 to 0.45 $\mu\text{g}/\text{m}^3$

The United Kingdom, Royal Commission on Environmental Pollution, 21st report "Setting Environmental Standards", Houghton (1998) also shows the reliance of epidemiology in setting such standards and outline the procedures followed. They are very similar to the USEPA. The Royal Commission also uses Benzene as an example, Figure 1.

There is no discussion at all in the EPA Benzene assessment about biological mechanisms. It is whole sufficient that consistent human studies and one dose-response relationship shows increases in leukaemia. A MEDLINE search reveals a large number of cytogenetic studies showing that Benzene enhances chromosome damage in animals, worker and human blood. None of these studies are cited in the EPA Assessment. The epidemiological studies provide the evidence that is necessary and sufficient for the carcinogenicity assessment. In 1982, IARC, a WHO department, declared Benzene a human carcinogen based on 5 epidemiological studies of Benzene exposed workers. Three show elevated leukaemia rates, and two show significant elevation of leukaemia.

It is stated in Figure 1 that human studies were more useful than animal studies. Most involved high occupational exposures that were probably under-estimated, making their results and over-estimate of the risk of effects. They refer to the Expert Panel on Air

Quality Standards (EPAQS) who considered that the risk of leukaemia in workers was undetectable when average exposure over a working lifetime is around 500 ppb.

BOX 2D	STANDARD FOR A GENOTOXIC CARCINOGEN: BENZENE
	<p>Sources of information Evidence of the harmfulness of benzene comes from both occupational exposure and laboratory studies. Tests on laboratory animals show that exposure to benzene increases the risk of certain types of leukaemia. <i>In vitro</i> testing indicates that benzene is a genotoxic carcinogen and may cause malignant disease even at very low levels of exposure.</p>
	<p>Epidemiological studies relate largely to occupational exposure. Short-term exposure to extremely high benzene concentrations, likely only as a result of an accident, may cause fatal narcotic or anaesthetic effects. For long-term exposures, the effect of most concern is non-lymphocytic leukaemia, initially described in workers exposed to very high concentrations, but subsequently confirmed in studies of workers exposed to much lower exposures.</p>
	<p>Key studies The human studies were more useful than the animal studies. Occupational exposures were probably under-estimated, so the risk of effects of exposure at a given concentration are likely to have been over-estimated. Nevertheless, several occupational studies gave reasonable estimates, especially two cohort studies giving evidence of an association between exposure to benzene and the likelihood of developing leukaemia.</p>
	<p>Conclusion of assessment The Expert Panel on Air Quality Standards (EPAQS) considered that a concentration of benzene in air can be identified at which the risks are exceedingly small and unlikely to be detectable by any practical method.</p>
	<p>From the available data, EPAQS concluded that the risk of leukaemia in workers is not detectable when average exposure over a working lifetime is around 500 ppb. To take account of the difference between a working lifetime (of approximately 77,000 hours) and chronological life (about 660,000 hours), the figure of 500 ppb was divided by 10. A further safety factor of 10 was applied in order to extrapolate from the fit, young to middle-aged male working population to the general population which might reasonably contain individuals unusually sensitive to the effects of benzene.</p>
	<p>An air quality standard of 5 ppb, as a running annual average, was therefore recommended. In making this recommendation, EPAQS considered that the uncertainties in the data were such that accurate extrapolation of risk from high occupational to low ambient exposure was impossible. Because, in principle, exposure to benzene should be kept as low as practicable, EPAQS adopted a pragmatic approach by recommending in addition a target standard of 1 ppb, as a running annual average.</p>

Figure 1: An example of standard setting using Benzene from the Royal Commission on Environmental Pollution, Houghton (1998).

Taking into account working lifetime (77,000 hours) compared with chronological lifetime (660,000 hours) the figure is reduced by a factor of 10. A further factor of 10 is applied to extrapolate from fit, young to middle-aged workers to the general population giving 5 ppb. Allowing for uncertainties in the ambient exposure, and following the principle of keeping exposure as low as practicable, a target standard of 1 ppb was adopted as a running annual average. This applies an overall safety factor of 500 below the NOAEL for exposed workers.

The UK report refers to the number and importance of international conventions relating to the environment. This includes the Maastricht Treaty which sets out the basis for the European Union's environmental policy, which includes protecting human health. The basic procedure of human health risk characterization is to compare the estimated human dose (EHD) of a given substance with either the no observed adverse effect level (NOAEL) or the lowest observed adverse effect level (LOAEL). The NOAEL is the greatest concentration of a substance that produces no observed adverse effect. The LOAEL is the lowest concentrate of a substance, found by experiment or observation that causes any adverse alteration of morphology, functional capacity, growth, development, or life-span, which is distinguishable from control organisms of the same species and strain.

For the epidemiology of human populations the NOAEL approach involves the search for the study with the lowest exposure which shows an adverse effect. Then a safety factor is applied to take into account the uncertainties, the susceptibilities and size of the exposed populations. The LOAEL approach uses dose-response relationships to determine the lowest threshold for the observation of an adverse effect. In using the epidemiological studies, careful consideration of bias and confounding is undertaken and then the Bradford Hill viewpoints are used to guide consideration of the likelihood of cause and effect, Figure 2.

In Figure 2, Houghton (1998) uses the term "criteria" and in the final quote the term "feature". The word very carefully chosen by Sir Austin Bradford Hill was "viewpoint". They are points from which to view the evidence and not criteria that must be achieved.

BOX 2C	ESTABLISHING CAUSE AND EFFECT
<p>If a clear and statistically significant association is observed between some form of health effect and some feature of the environment, the Bradford Hill criteria are used to help establish whether the relationship is one of cause and effect. The criteria examine the following features:</p> <p><i>strength of the observed association</i> <i>consistency of the observed association</i> <i>specificity of the observed association</i> <i>temporal relationship of the observed association</i> <i>presence of a dose-effect relationship (a biological gradient)</i> <i>biological plausibility</i> – this depends on the state of biological knowledge <i>coherence with the generally known facts of the history and biology of a disease</i> <i>(occasionally) experimental or semi-experimental evidence</i> <i>(in some circumstances) analogous observations.</i></p> <p>Bradford Hill stated that</p> <p>Clearly none of these nine [features] can bring indisputable evidence for or against a cause-and-effect hypothesis and equally none can be required as a <i>sine qua non</i>. What they can do, with greater or less strength, is to help us to answer the fundamental question – <i>is there any other way of explaining the set of facts before us, is there any other answer more likely than cause and effect?</i></p>	

Figure 2: The Bradford-Hill viewpoints for deciding on cause and effect from epidemiological evidence, Houghton (1998).

This is the importance of the note at the bottom of Figure 2. These are not "criteria", they are "viewpoints" with either greater or lesser strength from which we can decide "*is there any other way of explaining the set of facts before us, is there any other answer more likely than cause and effect?*". Epidemiology does not provide "scientific truth". It provides a weight of evidence that must be considered in an informed fashion, and decisions made with incomplete facts.

1.3 The Bradford Hill Guidance:

1.3.1 Viewpoints NOT criteria:

Establishing a cause and effect relationship is a judgment call made on a weight of evidence approach. Guidance as to how to weight the environmental epidemiological evidence is given by Sir Austin Bradford-Hill. Hill (1965) discusses the interpretation of epidemiological evidence from Association to Causation. In many assessments that

favour the RF-thermal approach and try to dismiss evidence of adverse health effects, Dr Bradford Hill's guidance is termed the "Bradford Hill Criteria". These are presented as a set of standards to be jointly achieved before a disease agent can be causally related to exposure. Sir Austin himself directly rejects this approach through the statement:

"Here are nine different viewpoints from all of which we should study association before we cry causation. What I do not believe - and this has been suggested - is that we can usefully lay down some hard-and-fast rules of evidence that *must* be obeyed before we accept cause and effect. None of my viewpoints can bring indisputable for or against the cause-and-effect hypothesis and none can be required as a *sine qua non*. What they can do, with greater or less strength, is to help us make up our minds on the fundamental question - is there any other way of explaining the set of facts before us, is there any other answer equally or more, likely than cause and effect."

Sir Austin also rejects strict statistical thresholds such as the 95% confidence interval. He cites a group of cotton mill workers who persistently showed more had respiratory disease than similar but unexposed workers but the difference was never statistically significant. He says that the evidence was so clear-cut that no formal test could contribute anything of value to the argument. It is also an absolute prerequisite that the exposure takes place prior to the effect occurring (**temporality**).

1.3.2 Specificity:

Specificity is valuable in situations where a specific disease agent is observed to produce a specific disease in specific workers exposed to a specific situation. Sir Austin says that when this occurs it is a strong argument in favour of cause and effect. He immediately cautions that we must not overemphasize this characteristic because many agents are known to produce more than one cancer or a range of illnesses. He also observed that many diseases are produced by multiple agents. The epidemiological evidence for EMR shows that it enhances a wide range of cancer and sickness in many body organs, under a wide range of exposure conditions across the spectral range. Sir Austin summarizes this with:

"In short, if specificity exists we may be able to draw conclusions without hesitation; if not apparent, we are not thereby necessarily left sitting irresolutely on the fence."

An application of specificity to EMR arises when we consider which body elements are particularly bioelectromagnetically sensitive and reactive. Our brains and hearts are immediately identified as sensitive organs. However all cells are sensitive, especially in the immune system and the endocrine system, through the actions of calcium ions and melatonin.

1.3.3 Experimentation:

Experimentation is not always possible but where it is it is very powerful. For example, in the Schwarzenburg shortwave radio tower study where a significant dose-response relationship for sleep disturbance was observed, confirmation of cause and effect came from turning the transmissions off for 3 days without notifying the residents. Sleep quality

improved significantly ($p < 0.001$), with a delay of about one day, especially in the lowest exposure group (Group C), showing that even though they experienced the lowest exposure, the RF signal was still interfering with their brains and their sleep. When the transmission was turned off permanently, measured human melatonin levels rose significantly (Prof. Theo Abelin pers. Comm.). This is a biological mechanism but it was not required for the assessment of cause and effect.

1.3.4 First Priority - Dose-Response Relationship:

In relation to dose-response Sir Austin states:

"If the association is one which can reveal a biological gradient, or dose-response curve, then we should look most carefully for such evidence. For instance, the fact that the death rate from cancer of the lung rises linearly with the number of cigarettes smoked daily, adds a great deal to the simpler evidence that cigarette smokers have a higher death rate than non-smokers." ... "The clear dose-response curve admits of a simple explanation and obviously puts the case in a clearer light."

Hence a dose-response relationship is highly indicative of a cause and effect.

1.3.5 Second Priority - Strength of Association:

For Strength of Association Sir Austin cites the example of John Snow's classic analysis of the cholera epidemic in 1854. He found 71 deaths per 10,000 in the group whose water came from the Southwark and Vauxhall Company and 5 deaths per 10,000 from those using the Lambeth Company, a factor of 14. No known biological mechanism was available at that time but this is sufficient to decide cause and effect, especially when the Lambeth Company water was sewage-free and the other Company's water wasn't.

Sir Austin warns, however, not to place too much emphasis on strength of association, for some important effects might wrongly be dismissed. He also dismissed the requirements to achieve statistical significance as an absolute requirement.

1.3.6 Third Priority - Consistency

Consistency is a feature to be specially considered. Has the effect been consistently observed to be associated in different persons in different places, circumstances and times? But consistency is not absolute. He states:

"Once again looking at the obverse of the coin there will be occasions when repetition is absent or impossible and yet we should not hesitate to draw conclusions."

For example, we cannot repeat the Korean War and wait another 20 years to see if cancer and sickness is greater in high exposure groups compared with low exposure groups. A repetition is impossible but the Polish Military or RF/MW exposed electrical workers can be used as comparisons.

1.3.7 Lowest Priority - Biological Mechanism:

Dr Bradford Hill's comments on "biological plausibility" or "biological mechanism" place them at the lowest priority. He states:

"It will be helpful if the causation we suspect is biologically plausible. But it is a feature I am convinced we cannot demand. What is biologically plausible depends on the biological knowledge of the day".

The absence of a detailed step by step biological mechanism is not a limitation on classifying chemicals, such as benzene, as carcinogens. A chemical that is observed to neoplastically transform cells (e.g. the Ames Test), produces tumours in laboratory animals and is associated with increased incidence of cancer in exposed workers, is classified as a human carcinogen. A good biological mechanism is evidence of genotoxicity. If a disease agent is genotoxic then it causes enhanced mutations, cancer and cell death rates.

Just two years ago Quinn (1997) noted that:

"Although the role of ultraviolet radiation in human skin carcinogenesis has been supported by a wealth of epidemiological data, the mechanisms by which it leads to skin cancer are still poorly understood."

It is accepted from the epidemiological evidence that UV radiation is carcinogenic, causing melanoma and other skin cancers. Sunburn of children and youths is a primary risk factor. Hence each summer the Cancer Society runs the "slip, slap, slop" and cover-up campaigns mainly targeting children in order to reduce the risk of skin cancer in later life. This is a strong reason for being very concerned about the depletion of the Ozone Layer and the formation of the "Ozone Holes" over the Arctic and Antarctic.

1.4 ICNIRP's an inappropriate reliance on a Biological Mechanism

In setting public health protection standards, epidemiological evidence is the strong guiding evidence that does not need a biological mechanism for it to be interpreted as probable or even cause and effect.

When the epidemiological evidence for cancer from EMR is of a higher standard of evidence than the current data from benzene, and many other chemical carcinogens, it is not scientifically credible for any authority to retain reliance on a single biological mechanism. In order for ICNIRP to retain its thermally based guideline it has had to apply criticisms to epidemiological and animal experiments and studies which are unacceptable anywhere else. The fundamental methodology of ICNIRP is wrong. It applies high levels of scientific rigor to individual epidemiological studies or laboratory studies, finding any shortcoming as an excuse to dismiss the whole project. This is not good public health science as is clearly illustrated by the Bradford Hill Viewpoints and the EPA Benzene example.

ICNIRP even uses deliberate misrepresentation. The whole ICNIRP human health assessment is scientifically fatally flawed as a public health protection approach.

One approach, that is commonly used by ICNIRP et al., is to define replication in terms are requiring exactly the same exposure conditions, animal species and data analysis and reporting protocols. With the myriad of variables in the EMR signal alone, with continuous,

pulsed, or FM modulation, that can have an almost infinite range of combinations of pulse frequency, duration, and amplitude, carrier frequency and intensity, modulation frequency and harmonics, etc.. When ambient temperature, local geomagnetic field components strength and orientation and state of solar activity are all considered, precise replication is impossible and unreasonable. These factors were worked out with the calcium ion efflux experiments. It is now an established biological mechanism, Blackman (1990) which has a complex set of exposure windows involving all of the exposure factors above.

On the other hand, when a laboratory shows a significant effect, such as single- and double-strand DNA breakage in microwave exposures, Lai and Singh (1996); then when an experiment is carried out with a much less sensitive assay and finds no increase in DNA strand breaks, Malyapa et al. (1998), then it is promoted as a replication that casts doubt on the original result.

The preconceived RF-thermal approach of WHO and ICNIRP assessors and commissioners also leads them to be selective and dismissive of strong evidence of nonthermal biological mechanisms. By normal scientific biological standards, one independent replication and/or extension can be sufficient to establish a biological mechanism. All of the following mechanisms have been observed in independent laboratories. For EMR we have several biological effects which significantly exceed this criteria, calcium ion efflux/influx, melatonin reduction, DNA strand breakage, chromosome aberrations, O.D.C. enhancement, enhanced proto oncogene activity and Schumann Resonance detection by human brains. These well established plausible mechanisms to support the epidemiological studies relating to cancer, reproductive, neurological, immune system and cardiac illness and death.

1.5 Cancer Epidemiology:

The science of epidemiology has developed to deal with complex human situations, as are found with almost every potential disease agent, whether it is chemicals, drugs, smoking, air pollution or ionizing radiation. Large groups of the population are identified whose occupation or activity involves exposure to the agent of concern. On some occasions the level of potential or probable exposure can be reasonably well stratified to allow a dose-response comparison to be made. In all cases, the exposure varies from day to day, week to week and year to year, and person to person. Hence there is a frequency distribution of hourly or daily exposures for each person and for each group. This frequency distribution accumulates towards a mean exposure. By judicious choice of occupational groups or residential situations the exposed groups can be dichotomized or stratified to allow the disease or mortality incidence differences to be detected if they do in fact occur.

For cancer studies a significant time delay between initiation and the development of malignant cancer can be many years or even several decades. Hence studies undertaken a few years after exposure are very unlikely to detect any increase in cancer, even in large populations. In small populations it is impossible because only a small proportion of people who are exposed show increased cancer at younger ages than about 50 to 60 years. As the total cancer rate increases with age in normal populations, especially after 50-60 years, it becomes harder to detect the influence of a specific carcinogen in older decadal age groups.

The accepted model of cancer development involves initiation, promotion and progression, Figure 3.

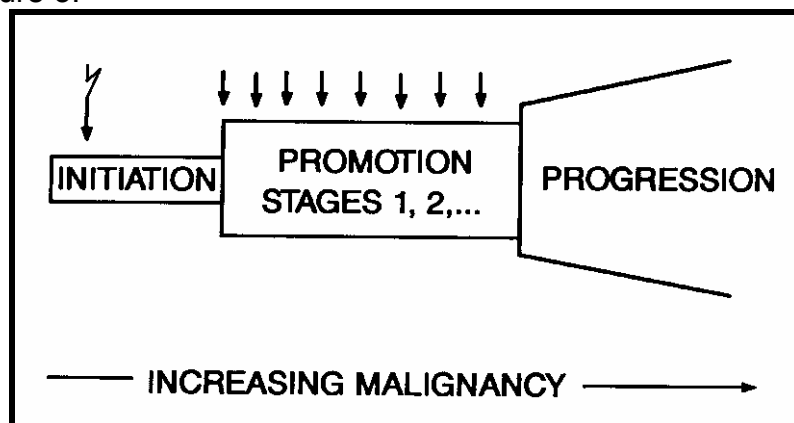

Figure 3: Model of multistage carcinogenesis. Initiation involves a single exposure to a carcinogen that damages the nuclear DNA. Promotion involves multiple exposures at certain intervals to agents that do not damage DNA directly. Many chemical promoters alter cell regulation through signal transduction or gap junction alteration. Promotion leads from benign to malignant tumours. Progression increases the degree of malignancy.

1.6 Exposure Dilution:

One of the fallacious reasons used to criticize and dismiss EMR epidemiological studies is that there is an unknown exposure regime between the occupational or military exposure at an early age and the health survey data decades later. The time delay is essential to allow time for cancer to develop. During the time between the initiating and promoting exposures and the collection of the health and mortality survey data, a complex exposure regime will be experienced by every person. The stochastic and randomized nature of this will dilute the differences between the groups and reduce any initial stratification or dichotomization based on the original exposure regime. Hence any adverse health effects observed will be significantly under-estimated. Thus, rejecting the study because of intra-exposure uncertainty is wrong and unjustified. In fact the effects seen can reliably be assumed to be even more elevated with higher significance than the analysis indicates.

The exposure complexity over decades significantly reduces the progressive exposure gradient that might have produced a dose-response curve. Thus any observed dose-response curve for cancer will be a very significant indication of cause and effect, even if it technically fails to achieve $p \leq 0.05$.

EMR is particularly problematic because it is ubiquitous. Every member of society is exposed to some extent. Epidemiological method aims to minimize the inclusion of confounding factors. Hence exposed populations are compared with controls who are as similar in as many respects as possible except of the exposure. Hence similarly trained and aged military groups are used as controls for radar exposed groups. In the Korean War Study, radar repairers were chosen as exposed groups and radio and radar operators as the comparison control group. Exposure surveys show that radio and radar operators are in a moderate exposure situation that is far higher than the general public. Hence if EMR exposure increases cancer, then the difference between the operators and repairs is not as great as the difference between both of them and the general male public of the

same age. In military and industrial situations this is another significant source of exposure dilution.

The technological advancements in society have exacerbated this further. Exposures occur from radio and TV broadcast towers, powerlines and home appliances. Computers, portable phones, mobile phones and cell sites have significantly raised individual EMR exposures in recent decades. Hence there is no true "no-exposure" population. These and other similar effects are strong sources of exposure dilution.

Almost all retrospective studies involve potential exposure estimates and not actual exposure. The skill is in selecting groups whose exposure frequency distribution gives a distinct difference in the mean exposure of most of the group. Once such a dichotomization is achieved it is totally inappropriate to dismiss any observed results based on the fact that they are only potential exposures and not actual exposures. A job exposure matrix can significantly reduce the uncertainties between groups classified by job. Such a survey was carried out in the Korean War Study. Despite this the authors try to claim that the observed adverse outcomes cannot be related to radar exposure since it was only based on potential exposure.

Thus all EMR studies have an extremely high probability of significantly under-estimating the Relative Risks.

The Korean War Study, Robinette et al. (1980), gives a good example. They surveyed exposures in a 5% sample of the "high exposure" repairers groups. They found frequency distributions within the three occupational groups being studied. This resulted in distinctly different distribution and mean Hazard Number for each occupational group that enabled a dose-response exposure gradient to be identified. The health and mortality survey data collected about 20 years later revealed a significant dose-response gradient in the mortality for each of the sailors surveyed when grouped in Hazard Number ranges. Despite 20 years of exposure dilution, the initial exposure dichotomy using occupational group produces elevated and significantly elevated mortality and morbidity differences 20 years later. Many of the elevated Relative Risks don't quite reach the $p \leq 0.05$ threshold. The exposure dilution effect is highly likely to raised them so that they do. This is accentuated by realizing that the comparison or control group was also regularly exposed and so this too produces its own exposure dilution effect, artificially reducing the observed RR and its significance.

A wide range of sicknesses, neurological and cardiac disease and death and cancer incidence and mortality in the Korean War Study, Robinette et al. (1980) and the Moscow Embassy study, Lilienfeld et al. (1978). Neither the authors of these studies, nor the WHO and ICNIRP assessors appreciate the effects of dilution for they found significant effects but sought to dismiss all evidence of adverse effects, even when the data and appropriate interpretations strongly clash with this.

1.7 Dr Goldsmith is critical of ICNIRP standards approach

Eminent internationally recognised environmental epidemiologist, the late Dr John Goldsmith, Goldsmith (1997c), states:

"To this day, the ICNIRP makes little use of epidemiological data, alleging that it is inconsistent and difficult to understand."

Dr Goldsmith's own conclusions, Goldsmith (1997b), after reviewing some of the epidemiological data on RF health effects include:

"Available data suggest that RF radiation be considered a carcinogenic risk, a position already taken in an internal U.S. E.P.A. document [Cited in Sibbison (1990)], in 1990 when there was much less evidence of the potential harmfulness of RF radiation."

Seeking more guidance from Dr Goldsmith on how to use epidemiological research in setting standards, this question is addressed in Goldsmith (1992). Dr Goldsmith was critical of approaches taken to date and identified problems including:

- (a) Failure to consider both thermal and non-thermal effects especially of non-ionizing radiation.**
- (b) Interpretation of non-significant results as equivalent to no effect.**
- (c) Accepting the author's interpretation of a study, rather than examining its data independently for evidence of hazard.**
- (d) Discounting data on unanticipated effects because of poor fit to preconceptions.**
- (e) Dependence on threshold assumptions and demonstration of dose response relationships.**
- (f) Choice of insensitive epidemiological indicators and procedures.**
- (g) Consideration of each study separately, rather than giving weight to the conjunction of evidence from all available studies.**

1.8 Dr Goldsmith reviews EMR epidemiological evidence:

Professor John Goldsmith was one of the world's most eminent environmental epidemiologists. A couple of decades ago when the International Society for Environmental Epidemiology was formed, Dr Goldsmith was invited to give the opening key note address to the first session of the first conference. This illustrates the high standing with which he is held in the international epidemiological and public health community.

Because of his standing the editor a new scientific journal, the International Journal of Occupational and Environmental Health, invited Professor Goldsmith to help to launch the first issue of the new journal by providing a significant review paper. The review, headed "Special Contributions" was carefully identified by Dr Goldsmith as an "opinion piece" which reviews and summarized the "Epidemiologic Evidence of Radiofrequency Radiation (Microwave) Effects on Health in Military, Broadcasting and Occupational Studies".

Goldsmith (1995, 1996 and 1997b) reviewed many epidemiological studies of radiofrequency and microwave exposures. Many of these studies show increases of cancer and some show increases of miscarriage and neurological effects. In all of these studies exposures involving heating are extremely rare and mean long-term exposures are a very small fraction of the heating threshold. Dr Goldsmith, Goldsmith (1995), concludes:

"There are strong political and economic reasons for wanting there to be no health effect of RF/MW exposure, just as there are strong public health reasons for more accurately portraying the risks. Those of us who intend to speak for public health must be ready for opposition that is nominally but not truly scientific.

At present there seems to be little interest in or understanding of epidemiologic information among regulatory bodies that should provide protection. While we conduct epidemiologic studies as well as we possibly can, we who are concerned with health protection and careful identification of risks must also keep pressure on the regulatory agencies to include epidemiologic thinking in their work."

From my experience in numerous cell site hearings and court cases I fully concur with Professor Goldsmith's conclusion. Expert witnesses who appear on behalf of telecommunications companies, including staff of the Australian and New Zealand Radiation Laboratories and the World Health Organization, dismiss health effects identified by epidemiology. They also dismiss effects shown by laboratory and animal experiments. They consistently support the position that there are only thermal effects and that adequate protection is given by adopting the ICNIRP guidelines and national standards that are based on avoiding heating effects. I strongly contend that this position is scientifically flawed and places public health severely and demonstrably at risk.

1.9 The Special case of Broadcast Tower Epidemiological Studies:

For residential studies around broadcast Radio and TV towers the cause and effect relationships can be much more decisive because to the complex nature of the radiation patterns. For example, antennae often focus the signal more in one direction than another. A cancer rate that is higher on the high emission side than the low emission side is a first indication of a dose-response. Radial ground level exposure levels vary with the antenna pattern and the frequency of the carrier. The higher the frequency the better the signal is focussed towards the horizon. The antenna elevation tilt is crucial in determining the position and strength of the main beam when it eventually strikes the ground several km from the base of the tower. Closer to the tower than this the exposure pattern varies with distance as the side-lobes intercept with the ground and the interference between the direct and reflected beams go into and out of phase.

Figure 4: A typical vertical antenna pattern for a 4-element dipole array at about 100 MHz.(VHF), Units in dB. Side-lobes have elevation angles of 72, 57, 15, 40,

15 and 8 degrees. For a the antenna at 500 m above ground level, the ground level side-lobe peaks occur at 160, 390, 600, 1870 and 3560 m from the base of the tower.

Figure 5 is street level measurements around the Empire State Building for a 44 MHz VHF transmitter, taken in 1933. These VHF signals have peaks inside 1 mile from the tower which are repeated near 2 4, 8, and 16 miles. Beyond 10 miles the signal generally declines as the inverse square law. Figure 6 shows the way in which VHF radial signal patterns, and hence ground level exposure intensity peaks and troughs, vary with carrier frequency. Cancer or other health effects which follow these complex patterns cannot be caused by any other confounder and hence firmly establish cause and effect. Epidemiologists and statisticians who are unaware of these patterns, such as Dolk et al. (1997a,b) and Selvin et al. (1992) made serious errors in the interpretation of their data by assuming a simple inverse square law in the first case and a linear relationship in the second. In both cases their leukaemia data follow a significant dose-response relationship in relation to mean exposure.

Figure 5: Ground level radiation pattern for the 44 MHz (VHF) signal from the Empire State Building in New York City, from Jones (1933) by merging his figures 6 and 8.

Figure 6: Variation resulting from field strength with distance and frequency.
Antenna height 1000', receiver height 30 ', power 1 kW, Reference data for Engineers, Jordon (1985).

Their weak and dismissive conclusions are favoured by ICNIRP but their data give conclusive evidence of cause and effect between RF radiation and cancer, especially for leukaemia, brain tumor and all cancer. These studies are supported by many other studies showing significant increases in these and other cancers in higher than average RF/MW exposures, and by established biological mechanisms.

1.10 Residential Exposure Factor:

We also have the significant difference between direct exposure intensity at a residential site from the tower, when people spend time inside and out, at home and away. Hence observed health effects need to be related to a residential exposure estimate which takes into account these factors.

When considering cancer, the appropriate exposure metric is the cumulative personal exposure over many years as this relates to cumulative cell damage. The long-term cumulative exposure is the product of time and mean personal exposure. The mean personal exposure is a combination of indoor/outdoor and home/away times. Based on local measurements, the indoor exposure is assumed to be 1/100th of the outdoor exposure. The away exposure is assumed to be 1/150th of the home exposure. Taking the indoor/outdoor ratio as 20:4, the weekly home/away ratio as 108:60 and annual ratio of 44:8. This produces a personal exposure factor of 0.098, which is rounded up to 0.01. Thus the residential exposure factor (REF) is taken to be 1 % of the direct exposure.

People who happen to live in a radial ring with very low local exposure, will have lower mean exposures than those who live on either side of the dip. However, since their local movements take them regularly through the higher exposure zones, their mean exposure will be a little higher than indicated by the estimates above. This won't be by much because of the dominance of the inside at home period.

Cancer latencies and dilution will also reduce the size of the RR and its significance, underestimating the magnitude of any observed adverse health effects in residential studies.

The WHO and ICNIRP assessments suffer from all of the problems identified by Dr Goldsmith and Sir Austin Bradford Hill. This critique attempts to correct this and to incorporate epidemiological evidence into processes for setting public health protection standards.

A totally new, fresh and objective scientific approach is needed to be taken to more comprehensively and reliably assess the research results that have been published. A scientifically objective and open-minded approach should start with some open questions. These questions would include:

What is the evidence of biological effects and adverse health effects, and what does this evidence suggest in terms of potential, probable or actual adverse health effects?

After consideration of the epidemiological evidence for RF/MW exposed populations, a similar approach will be taken and conclusions given on appropriate public health exposure standards. In the mean time the history of the RF-Thermal View is outlined to document its source and basis.

2. History of the RF-Thermal View:

2.1 A long-held Western mind-set:

ICNIRP follows a long-held Western position that initially ignores epidemiology and concentrates solely on a particular biological mechanism. It is demonstrable that acute high level exposure causes Tissue Heating. Exposed people and animals have their temperature measured and it rises. This is shown reliably and repeatably. It makes sense. Given the central and dominating role of the RF-Thermal View it is important to trace its history.

In the period immediately following the Second World War, when radio and radar had come into widespread use for the first time, there was no epidemiology to challenge the developing view that Tissue Heating was the only possible effect. Early on there were anecdotal, case-by-case reports of leukaemia, ocular defects, reproductive problems, heart problems and neurological symptoms of tiredness and headache. For example, McLaughlin (1953), Cleary and Pasternack (1966), Rosenthal and Beering (1968), Forman et al. (1982), and Archimbaud et al. (1989). Some of these involved quite high acute RF/MW exposures. Most were relatively isolated and they were claimed by some to not be confirmed to be RF/MW related.

2.2 The U.S. Tri-Service Program:

The conviction that the only possible effect of RF/MW exposure is tissue heating is sourced largely from the Tri-Service Program. One of the primary aims was to determine the thermal threshold so that exposed personnel could be protected from dangerous over heating. This is documented through Steneck et al. (1980) and published conference proceedings from the United States. Steneck et al. document the detailed history of the development of the U.S. standard C95.1. They note that Dr John T. McLaughlin, a medical consultant of the Hughes Aircraft Corporation assessed the research into the ill effects of radar exposure. He wrote and sent a report to the military that listed purpura hemorrhagica (internal bleeding), leukaemia, cataracts, headaches, brain tumors, heart conditions and jaundice as possible effects.

No weight was given to this report and calculations proceeded to determine the heating exposure that people could tolerate, based on their ability to deal with solar radiation. After some basic arithmetic errors were corrected a figure of 10mW/cm^2 was arrived at in about 1960. This became the basis of C95.1 ten years later, supported by a large body of research that was coordinated through the Tri-Service Program. Steneck et al. summarized this research, pointing to the high acute exposures that were involved.

2.3 The U.S./U.S.S.R. double standard:

In 1970 Dr Leo Inglis presented a paper to an IEEE forum on EMR entitled "*Why the double standard - a critical review of Russian work on the hazards of microwave radiation*". He notes that a major difference between the U.S. and Soviet work was:

"In the U.S., the thermal effects are generally believed to be the only ones of significance; other contentions are usually dismissed as lacking a provable basis. In the U.S.S.R., non-thermal effects are considered the most significant and are overwhelmingly the ones most studied."

2.4 Determining and challenging the thermal threshold:

The Thermal View dominance is confirmed in the proceedings of the 1974 conference on "*Biological effects of Non-Ionizing radiation*", held at the New York Academy of Sciences, 12-15 February 1974, and published in Annals of the NY Academy of Sciences, February 28, 1975. The conference chairman was Dr Paul E. Tyler of the EMR project office in the Dept of the U.S. Navy. His opening remarks include comments about the Tri-Service Program and the very high levels of exposures generally used. He states:

"After I had read and analyzed of the publications for this program (the Tri-Service Program), I was left with the feeling that the research was conducted with the preconceived idea that all of the effects were thermal in nature. It appears that the protocols were designed only to determine gross thermal effects."

"Although the Tri-Service research addressed essentially only the problem of thermal hazard, the idea that the sole hazard was thermal became dominant, and in the early 1960's, an air of complacency settled over this country. At the end of the Tri-Service Program in 1960, United States research in this area decreases to a very low level and remained there for the next decade."

The general acceptance or complacency about the RF-thermal view was scientifically challenged time and time again throughout this period. For example, Dr Adey gave the introductory paper to this 1974 conference, on the effects of EMR on the nervous system. In this paper he states:

"Even a recent review body of the World Health Organization decided after discussion to dismiss from its concerns possible biological effects that might occur in the absence of significant heating. It has become clear, however, that interactions with the mammalian central nervous system can be reliably produced by oscillating electric and electromagnetic fields without significant heating of tissues."

It is a very strong statement to say that interactions can be reliably produced in the CNS without heating of tissues. Dr Adey refers to the work of König and Wever in Germany and to work from his own laboratory, on behavioural effects such as changed reaction times and altered circadian rhythms in ELF exposures. These effects were associated with induced electric field gradients in monkey phantoms in the range 0.1 to 0.01 μ V/cm. The effects were also linked to changes in EEG and significant effluxes of calcium ions and GABA, Kaczmarek and Adey (1973). During the 1970's it is shown that calcium ion efflux occurred at non-thermal exposure levels and was primarily related to modulation frequency, i.e. a non-thermal biological mechanism.

Two large epidemiological studies were carried out in the 1970's, Lilienfeld et al. (1978) and Robinette et al. (1980) in the middle of the Cold War. These found small but significant increases in cancer, cardiac problems and neurological symptoms. However, the authors were under strong pressure, for a range of reasons, to not relate these results to the radar exposure. In one case, Lilienfeld et al., the U.S. State Department case officer, Dr Herbert Pollock, actually changed the conclusions, Goldsmith (1997).

Tell and Harlen (1979) outline the Thermogenic properties of RF/MW. From a number of studies that recorded rectal temperatures under various exposure conditions. This was to give guidance in setting RF/MW exposure standards. The 10 mW/cm² standard was confirmed as protecting from temperature rise of less than 1°C.

2.5 An official attempt to declare EMR carcinogenic:

In 1990 an internal review team of the U.S. E.P.A. recommended that ELF be classified as a probable human carcinogen and RF/MW as a possible human carcinogen. Under pressure from the Bush White House, EPA administrators changed the conclusions of the review and the classification never became official EPA policy, Sibbison (1990). The rationale was based on the preferred public policy stance "We don't want to scare the public".

2.6 U.K.'s NRPB retains the RF thermal view (1991):

In May 1991 the United Kingdom's NRPB issued a series of reports on EMR, which included a report on the Biological Effects of ELF, Sienkiewicz, Saunders and Kowalczyk (1991) and the Biological Effects of RF/MW, Saunders, Kowalczyk and Sienkiewicz (1991). This second report reviews many cell and animal studies which used thermal exposures and produced some observable effects which were not seen when SAR's dropped below 4 W/kg, e.g. behavioural effects. They don't find anything reliably significant in the long-term mouse study of Guy et al. (1985) in which found a significant increase in primary malignant tumors at an SAR of 0.4 W/kg. The U.S. E.P.A. internal review team found this study much more relevant and use it as part of their recommendation to classify RF/MW as a possible human carcinogen, McGaughy et al. (1990). Epidemiology played no role at all in the NRPB review, which was solely concerned with biological mechanisms. However it played a major role in the EPA review.

2.7 U.S.'s IEEE/ANSI review retains RF Thermal View (1993):

In 1993 the U.S. based IEEE published their revision of the IEEE/ANSI RF/MW standard C95.1-1991, IEEE(1991). This report is solely about thermal biophysical interactions that create heat and the SAR levels that will avoid dangerous heating, burns and shocks. The assessment criteria all related to thermal absorption mechanisms. The primary revision is a relaxation of power density limits for all body parts except eyes and testes. This relates to a revised calculation of the 6-min dose that produces an SAR of 0.4 W/kg.

Of all the major western authorities who are responsible for setting RF/MW exposure standards, the only body which is departed from solely considering thermal effects, as an internal review team of the U.S. E.P.A.. They also considered epidemiologic and animal evidence at non-thermal levels which did involve increases in cancer. However, they

were not allowed to retain their recommended carcinogenic classification because EPA administrators bowed to political pressure.

3. The ICNIRP and WHO Approach in the 1990's:

The world Authorities, WHO and ICNIRP, in the early and late 1990's, also retain the RF-Thermal View and recommend guidelines based on avoiding heat. They have undertaken more comprehensive reviews that considered epidemiological and long-term animal evidence. Their reviews of this evidence did not sway them from the RF-Thermal View. A detailed analysis of their reviews and the research papers cited reveals evidence of predetermination to reject any evidence that contradicted this view. The long history of holding the RF-Thermal View has brought extensive comfort and complacency. This is partly through the great degree of precision, repeatability and reliability of SAR calculations and heat protection. This is such a long-held view that it has become a mind-set. This way of thinking makes it extremely difficult to move review teams from the RF-Thermal View to the Public Health Protection approach. It requires a complete change of thought and approach to move from a comfortable and well understood mechanism to the much more complicated consideration of epidemiological data derived from complex human situations. But, as Dr Lilienfeld reminded us:

"The proper study of man is man".

3.1 The Constructive Dismissal Approach:

In order to maintain the RF-Thermal View against the extremely strong evidence from epidemiology, animal experiments and of non-thermal mechanisms, the WHO and ICNIRP assessors and their colleagues have developed a set of dismissive methodologies. These include:

- Maintaining that the RF-Thermal view as the "consensus of science". This allows the biological mechanism to dominate and epidemiology and animal evidence is dismissed.
- Maintaining a contrast between Ionizing radiation and Non-ionizing radiation.
- Moving the level of evidence goalpost where for a study to become "evidence" it must first be replicated, whereas in the past each study was evidence and replication was required to "establish" a biological effect.
- Promoting strict sets of scientific criteria which are proposed as being necessary for reliable use of the results, e.g. the Bradford Hill "criteria", instead of "viewpoints", and Dr Martin Meltz's 13 experimental criteria for testing genotoxicity, Meltz (1995). In this way all non-thermal evidence is rejected.
- Citing studies which are too small and have small follow-up periods so there is little or no opportunity for cancer to develop, as evidence that radar exposure does not cause cancer.

- Citing studies which do show significant increases in cancer as showing no evidence of increases in cancer.
- Preferring to simply quote the conclusions of papers and reports that state that there were no adverse effects found, while failing to recognize that the data and analysis within the documents do show significant associations, including significant dose-response relationships.
- Dismissing epidemiological studies on the grounds that populations and exposures are not well defined. Lilienfeld explains that this is a difficulty but results are still relevant and important.
- Dismissing research results one by one and failing to assemble and interpret the whole pattern of research results - the divide to conquer approach.

All of these are demonstrated methods used by WHO and ICNIRP which amounts to a systematic approach to wrongly dismiss evidence of effects, i.e. Constructive Dismissal.

3.2 The evidence of a leading WHO/ICNIRP member:

Hence in the 1990's a major WHO review was published, WHO (1993) and the latest ICNIRP Guideline assessment has been published, ICNIRP (1998). Both of these maintain the RF-Thermal View. A leading scientist who has been involved in chairing both the WHO review team and technical editor of the review, and was chairman of ICNIRP until April 1996, and now is Chairman emeritus, is Dr Michael Repacholi.

Insights into his mind-set, which is reflected by WHO and ICNIRP, is seen in his evidence in a New Zealand cell site case, the MacIntyre Case, November 1995. In this case the local residents of the suburb of Ilam, in Christchurch, New Zealand, appealed a City Council decision to allow a cell site to be installed on the roof of an old suburban movie theatre. The site would irradiate a number of local residences and the local kindergarten that was about 70 m from the site.

Dr Repacholi appeared in this case as an expert witness on behalf of BellSouth Ltd,. In sworn testimony contained in his evidence-in-chief he states: (Note that the emphasis on 'any' is Dr Repacholi's)

"To produce any adverse effect, RF exposure above a threshold level must occur. This threshold level is the RF exposure needed to increase tissue temperature by at least 1°C."

"Multiple exposures to sub-threshold levels of RF have not been found to have any adverse health impact."

"Exposure to RF fields has not been established to cause cancer."

"No accumulation of damage occurs to tissues from low level (sub-threshold) RF exposures".

"The science has also not found any evidence for adverse health effects from repeated exposures at levels below the threshold."

Dr Repacholi's evidence is fully consistent with the ICNIRP conclusions outlined above and were referenced by Dr Repacholi to the WHO/IRPA/UNEP review, WHO(1993). This was prepared by a WHO/IRPA task group that was chaired by Dr Repacholi. He was also the scientific editor of the report.

To back up Dr Repacholi's claim that the RF-Thermal position was the "consensus of science", Dr Repacholi referenced WHO (1993), for which he had a major responsibility.

3.3 What is "evidence" vs "established"?

Around the time of this court case Dr Repacholi was supervising a research project in Australia in which genetically modified mice were exposed to a sub-thermal dose of a GSM cell phone signal, for two half-hour periods per day. This gave SARs averaging 0.13 to 1.4W/kg during exposures, giving a daily average range of 0.005 to 0.058W/kg. They concluded that "Lymphoma risk was found to be significantly higher in the exposed mice than in the controls (OR = 2.4, $p=0.006$, 95%CI: 1.3-4.5)."

Hence Dr Repacholi's own research results, which were published after the NZ court case was concluded, contradict his claims in court. In an industry-sponsored press conference in Vienna at the time of the Vienna EMR Workshop in October 1998, Dr Repacholi stated that there was no evidence of adverse effects from GSM cell phones. When questioned in the Workshop about his own research, he took the position that a scientific experiment can only be considered as "evidence" once it has been independently replicated. This is not the definition of "evidence" which most people and most courts accept. A research result is "evidence". Replication is required in order to establish a biological effect. Both the original and the replicate experiments contribute evidence with amounts to the establishment of a biological effect.

Two other long-term rodent studies have observed increases of cancer in exposures involving RF/MW. Chou et al. (1992) chronically exposed rats to a non-thermal radar-like signal, observed a significant increase in benign tumors and highly significant increase in primary malignant tumors, $RR=3.6$, 95%CI: 1.34-9.7, $p=0.0036$. Vijayalaxmi et al. (1997) exposed cancer-prone mice to a 2.45 GHz continuous wave signal and observed a 41 % increase in tumors and highly significant increases in chromosome damage in bone marrow and blood.

Hence the evidence contains three studies in which RF/MW radiation significantly increases cancer in rodents, including one which also associates this with chromosome damage. The combination of tumor increase with chromosome damage is evidence of genotoxicity. These projects serve to illustrate one of the fundamental problems with EMR research. While three independent laboratories have observed increases in cancer in rodents with RF/MW exposures, all rodent species were different, all exposure regimes were different. One was a GSM carrier of 900MHz pulsed at 217 Hz for 2 periods of half an hour per day with mean daily SAR in the range 0.005 to 0.058 W/kg. Two used 2.45 GHz carriers but the first was pulsed at 800pps, modulated at 8 Hz, and involved 21.5hr of daily exposure with a daily mean SAR in the range 0.13 to 0.36 W/kg. The second used a continuous wave exposure for 20 hr/day with a daily average SAR of 0.83W/kg.

For those, like ICNIRP, who maintain the RF-thermal view, these projects do not provide "evidence" that RF/MW produces cancer in rodents because every experiment has differences in animals and exposure regimes and none have been precisely replicated.

Alternatively, taking the more traditional scientific and legal approach, there are three studies, from independent laboratories, which show significant increases in cancer in rodents at non-thermal levels of exposure to RF/MW radiation. Hence there is animal evidence to support the epidemiological evidence that RF/MW exposed populations develop significantly higher rates of cancer incidence and mortality. Both the animal evidence and the human evidence covers a wide range of RF/MW exposure conditions. Across the same frequency range multiple independent laboratories have observed significant DNA-strand breakage and enhanced chromosome aberrations. Hence there is strong evidence that RF/MW is mutagenic, carcinogenic and teratogenic in animals and people at non-thermal levels of RF/MW exposure.

3.4 Ionizing Radiation vs Non-Ionizing Radiation?

The history of EMR shows that it has always been treated differently from chemicals. One reason for this is an argument related to radiation. This runs as follows: Ionizing radiation produces free radicals in cells, enhances the damage to DNA and other macromolecules which increases the risk of cancer because the repair mechanism makes more mistakes. Non-Ionizing radiation does not produce free radicals therefore cannot damage DNA and cannot cause cancer.

We can immediately note that UV-B radiation is non-ionizing but it is known to cause cancer. Many chemicals cause cancer, such as benzene, without involving ionization. It is now established and widely accepted, that solar UV radiation which reaches the ground causes cancer, particularly skin cancer. Among a number of identified mechanisms is UV's ability to cause mutation in the tumor suppressor gene p53, Leffell (2000). This proves that non-ionizing radiation does cause cancer and acts through altering the p53 gene activity. This illustrates the point that cancer is caused by both enhancing cell damage and inhibiting cell damage repair rates and efficiencies.

There is evidence that non-ionizing radiation dose enhance free radical activity. Phelan et al. (1992) investigated membrane fluidity in Melanin-containing cells that were exposed to low level microwave radiation, 1 hr at 0.2 W/kg. They conclude:

"The data indicate significant, specific alteration of cell-membranes was due, at least in part, to the generation of oxygen radicals".

Lai and Singh (1997) showed that significant microwave induced DNA-strand breakage could be eliminated through the application of either melatonin, a natural free radical scavenger and PBN, a spin-trap compound.

Hence UV-B and RF/MW non-ionizing radiation are both associated with enhanced free radical activity in cells, either by enhancing the free radicals or by reducing the free radical scavenger, melatonin.

Hence the effect on ionizing and nonionizing radiation can be very similar, but may involve different mechanisms. Either way, the effect is the same. They both produce genetic damage and are carcinogenic.

3.5 Ionization is not a prerequisite for cancer:

Many generations of medical biologists and toxicologists do not assume that ionization is a necessary prerequisite for cancer producing agents since thousands of chemicals are cancer producing agents without the involvement of ionization. Chemicals are carcinogens, Baxter (1995), when they:

- A. Alter DNA, initiating cancer.
- B. Corrupt cellular growth control, thus acting as cancer promoters.
- C. Act with other carcinogenic agents, working as Co-promoters of cancer.

There is evidence that EMR acts in all of these ways.

3.6 Examples of extreme lengths gone to retain the RF-Thermal view:

ICNIRP and individual national authorities are so wedded to the RF-Thermal view that they not only attempt to reject studies by claiming weakness and inconsistencies, they also descend to use demonstrably incorrect scientific statements.

3.6.1 ICNIRP misquotes results:

In the ICNIRP (1998) cancer assessment the following statement appears:

"More recent studies have failed to show significant increases in nervous tissue tumors among workers and military personnel exposed microwave fields (Beall et al. 1996 and Grayson 1996)."

Statistical significance is defined as $p \leq 0.05$ and/or a 95% confidence interval where the lowest side of the range is close to 1.0 or higher. Beall et al. studied the increase in brain tumor with exposure to computer monitors (VDTs). Their abstract states:

"Other results included and elevated OR for 10 or more years of employment in engineering/technical jobs [OR = 1.7; 95% confidence interval (CI) = 1.0-3.0] or in programming jobs (OR = 2.8, 95%CI= 1.1-7.0). The OR for glioma for all subjects who had accrued 5 years of programming work 10 years before each case's death was 3.9 (95%CI = 1.2-12.4)."

The data in the paper show that for engineering/technical jobs there is a dose response for brain tumor death and years of work, $p=0.07$, and for computer programming, $p=0.04$. Thus the paper does show significant increases in brain tumor death from exposure with dose response and one significant dose response relationship.

Grayson (1996) investigated a large sample (880,000 with 11.17 million p-yrs) of U.S. Air Force personnel, some of whom were occupationally exposed to EMR and ionizing radiation, with exposure assessed through a job exposure survey. From this very large sample only 275 were exposed to RF/MW, 94 of whom developed brain tumors. This yielded OR = 1.39, 95%CI: 1.01-1.90. This is a statistically significant result.

ICNIRP's statement about Beall et al. (1996) and Grayson (1996) is demonstrably scientifically wrong and misleading. It reveals a clear predetermination to dismiss evidence of effects.

3.6.2 In New Zealand a similar situation occurred:

Late in 1998 the Royal Society of New Zealand released a review report on radiation health effects. Being the Royal Society it was assumed that it would be a high quality, up to date and authoritative publication. The report was entitled "Radiation and the New Zealand Community - A scientific Overview". The major contribution of two staff members of the National Radiation Laboratory resulted in statements about the health effects of EMR being totally wrong and misleading.

The N.Z. Royal Society report contains all of the omissions, biases and errors shown below in the preparation of the ICNIRP guideline and the WHO/UNEP/IRPA review. It takes the thermal view and at one key point makes the claim in relation to ELF EMR, p67:

"Some questions have been raised with respect to possible adverse effects of electric and magnetic fields, particularly those at low frequencies, in connection with high voltage lines, computer terminals, domestic appliances and wiring. However, no effects due to occupational exposure have been reported, nor are there any indications of adverse health effects on humans, other than from spark discharges and shock from direct contact."

It is glaringly untrue to state that "no effects due to occupational exposure have been reported". Many hundreds of studies have reported ELF biological and human health effects. Three have been carried out in New Zealand. Preston-Martin et al. (1993) found for all brain cancer elevated risks were found for electrical engineers (OR= 8.2, 95%CI: 2.0-34.7) and electricians (OR = 4.6, 95%CI: 1.7-12.2). Beale et al. (1997) investigated health effects near high voltage powerlines in Auckland and found significant linear dose-response relationships for some health and psychological variables and magnetic field exposure. Dockerty et al. (1998) studied childhood cancers in relation to EMF exposure. Electric blankets produced elevated adjusted rates of leukaemia (OR= 2.2, 95%CI: 0.7-6.4), CNS cancer (OR = 1.6, 95%CI: 0.4-7.1) and other solid cancers (OR = 2.4, 95%CI: 1.0-6.1). Leukaemia risk was highest when bedroom magnetic field was $\geq 0.2\mu\text{T}$ compared with $\leq 0.1\mu\text{T}$, (OR= 15.5, 95%CI:1.1-224).

A totally independent team of Swedish medical scientists, reviewed over 100 epidemiological papers published up to July 1994, Hardell et al. (1995). They concluded:

"Epidemiological and experimental studies concerning extremely low frequency electromagnetic field exposure and malignant diseases published up to 1 July 1994 were evaluated to assess the possible carcinogenicity of electromagnetic fields and the scientific basis for environmental and occupational standard setting. We concluded that there are possible associations between

- (i) **an increased risk of leukaemia in children and the existence of, or distance to, power lines in the vicinity of their residence,**
- (ii) **an increased risk of chronic lymphatic leukaemia and occupational exposure to low frequency electromagnetic fields and,**

- (iii) **an increased risk of breast cancer, malignant melanoma of the skin, nervous system tumours, non-Hodgkin lymphoma, acute lymphatic leukaemia or acute myeloid leukaemia and certain occupations.**

There is no scientific basis for occupational or environmental standard setting for low frequency electric or magnetic fields."

The final statement about standards setting, is based on the lack of good exposure measurement in most occupational studies and the lack of dose response relationships in order to determine an ELF field level which will avoid the observed association to risk factors. The fact that the mean daily exposure of even the highly exposed workers is a small fraction of the current standards demonstrates the gross inadequacies of the standards and guidelines. The 1990 IRPA/INIRP guideline, Jammett et al. (1990), recommends a 24 hour occupational limit of 500 μ T and residential limit of 100 μ T.

Many more ELF health studies have been published since July 1994. Four laboratories have shown that ELF below 1.2 μ T reduces the oncostatic protection of melatonin in human breast cancer cells, with a threshold of around 0.1 to 0.2 μ T. Also 4 laboratories have shown the ELF radiation is associated with significant increases in DNA strand breaks. One replication is usually necessary to confirm a biological effect. Four independent studies definitely establish a biological effect. These biological effects are biological mechanisms which confirm the plausibility of the epidemiological associations found in Hardell et al. (1995), giving the classification to the level of probable or actual human carcinogen with the addition of the post-1994 studies.

Residential powerline studies on childhood leukaemia, such as Feychting and Ahlbom (1993), found for a cut-off point of 0.2 μ T a Relative Risk of RR=2.7 (95%CI: 1.0-6.3) and a trend with p=0.02. For a cut-off point of 0.3 μ T, RR= 3.8 (95%CI: 1.4-9.3, for the trend p= 0.005 . By pooling data from Norwegian and Swedish studies, Feychting et al. (1995) found a relative risk of RR=2.0 (95%CI: 1.0-4.1) for a 0.2 μ T cut-off and RR=5.1 (95%CI: 2.1-12.6) for 0.5 μ T of, a significant dose response relationship, p=0.03.

Hence it is now possible to determine that a current threshold level for no observed effect for childhood leukaemia and breast cancer is near 0.1 μ T. This is 1000 times below the current guideline and has yet to have a safety factor incorporated.

Thus it is grossly wrong for the report of Royal Society of NZ to claim that "no effects have been reported from occupational exposure" and "nor are there any indications of adverse health effects on humans, other than from spark discharges and shock from direct contact". This is so grossly misleading and dishonest, that it puts this report's credibility, and that of the Royal Society of New Zealand, seriously at risk. In coming to its conclusions the Royal Society of NZ relied heavily on the Director of the National Radiation Laboratory, Dr Andrew McEwan.

Scientists and the public expect much more scientific accuracy and integrity from Government employees who advise the Minister of Health, and of the Royal Society.

3.6.3 Canada does it a bit better:

In contrast, the Royal Society of Canada in their March 1999 report "Potential health risks of Radiofrequency fields from wireless telecommunication devices", carried out a detailed review of biological mechanisms. They involved current researchers in the review team who concluded that most RF exposures used in experiments exceed the limits set in the Canadian Safety Code 6 (SAR = 0.08 W/kg). They also state:

"However, effects on cell proliferation, Ca^{2+} efflux, blood brain barrier (BBB) permeability, behaviour and ornithine decarboxylase (ODC) activity have all been repeated in independent laboratories. Because these effects occur at exposures not thought to elicit thermal effects, it is likely that these effects, even if they also occur at higher exposure levels, are non-thermal biological effects."

This critique will show that some key non-thermal biological mechanisms are well established by replication in many independent laboratories. These established biological mechanisms are totally supportive of and consistent with a large body of epidemiological evidence, which includes many statistically significant associations and dose response relationships. In doing so this critique will show that the ICNIRP assessment takes a predetermined dismissive approach that is highly selective and unscientific. It even involves deliberate and repeated misquoting and misrepresentation of study results. It becomes clear that the thermally based guideline is being defended at all costs, even at the cost of putting public health severely at risk all around the world.

4. ICNIRP's 1998 assessment of the RF/MW Guideline - Conclusion:

The failure to use epidemiological and animal evidence as the primary source, and the predetermination to retain of the RF-Thermal View is seen in the conclusions of ICNIRP (1998), p507:

"Data on human responses to high-frequency EMF that produce detectable heating have obtained from controlled exposure of volunteers and from epidemiological studies on workers exposed to sources such as radar, medical diathermy equipment and heat sealers. They are supportive of the conclusions drawn from laboratory work, that adverse biological effects can be caused by temperature rises in tissue that exceed 1°C. epidemiological studies on exposed workers and the general public have shown no major health effects associated with typical exposure environments. Although there are deficiencies in epidemiological work, such as poor exposure assessment, the studies have yielded no convincing evidence that typical exposure levels lead to adverse reproductive outcomes or an increased cancer risk in exposed individuals. This is consistent with the results of laboratory research on cellular and animal models which have demonstrated neither teratogenic nor carcinogenic effects of exposure to athermal levels of high frequency EMF."

You can see the use of the Constructive Dismissal approach that results in retention of the thermal-based guideline. Apart from the statement about there being adverse effects of tissue warming, every other statement made is scientifically challengeable and misleading.

For example: "epidemiological studies on exposed workers and the general public have shown no major health effects associated with typical exposure environments".

Epidemiological studies of exposed workers and the general public have shown significant increases in major health effects, including dose-response relationships which are indicative of a casual effect. This includes multiple studies on miscarriage and significant dose-response relationship between microwave exposure and first trimester miscarriage, Ouellet-Hellstrom and Stewart (1993). Many laboratory studies on cells and animals have demonstrated athermal carcinogenic and teratogenic effects, Chou et al. (1992), Repacholi et al. (1997), Vijayalaxmi et al. (1997) and Magras and Xenos (1997). These statements are demonstrably incorrect and misleading. It is conclusions such as these that continue to put thousands of lives at risk in New Zealand alone, and millions at risk around the world. Many occupational studies have found significant increases in cancer, e.g. Lilienfeld et al. (1978), Robinette et al. (1980), Milham (1985 a,b, 1988), Thomas et al. (1987), Demers et al. (1991), Cantor et al. (1995), Szmigielski (1996), Grayson (1996), Beall et al. (1996). Residential studies showing significant increases in cancer from RF/MW exposure, some of which show significant dose-response relationships include: Hocking et al. (1995), Selvin et al. (1992), Dolk et al. (1997a,b), and Michelozzi et al. (1998).

In the middle of the frequency spectrum, where the ICNIRP Guideline exposure level is at its lowest, $200 \mu\text{W}/\text{cm}^2$, there are residential epidemiological studies that give dose-response relationships for adult and childhood leukaemia with a threshold near $0.025 \mu\text{W}/\text{cm}^2$. This is 8,000 times lower than the ICNIRP Guideline. In Switzerland, significant sleep disturbance was observed at an RF exposure level of $0.0004 \mu\text{W}/\text{cm}^2$, Altpeter et al. (1995). For this RF frequency (6.1-21.8 MHz) for which the ICNIRP Guideline is $2000 \mu\text{W}/\text{cm}^2$. The adverse effect occurs at a factor of 5 million times lower than the Guideline.

By ignoring the epidemiological evidence ICNIRP settles on a thermally-based guideline by accepting a thermal threshold of $4 \text{ W}/\text{kg}$, a workers safety factor of 10 ($0.4 \text{ W}/\text{kg}$) and a further factor of 5 for the general public ($0.08 \text{ W}/\text{kg}$). This is plotted in Figure 2 in terms of electric field strength and exposure intensity, as a function of carrier frequency.

Figure 7: The ICNIRP Guideline for public and occupational exposures as a function of carrier frequency. On the left the units are electric field strength (V/m) and on the right the exposure intensity ($\mu\text{W}/\text{cm}^2$). The three plateau regions above 1 kHz are 87, 28 and 61 V/m, corresponding to 2000, 200 and 1000 $\mu\text{W}/\text{cm}^2$, respectively.

The ICNIRP methodology and use of scientific research is blatantly incorrect. A long-held mind-set dominates the EMR radiation authorities that needs to be exposed and changed.

5. A sports analogy of the different approaches:

A primary issue in this report is the understanding of, and resolution of the position of ICNIRP in the face of the large body of scientific evidence that is available. ICNIRP doggedly retains the RF-Thermal view and rejects any challenge, despite the nature and strength of the evidence. For every other potential disease agent the standards setting process relies most heavily on epidemiology. ICNIRP rejects all epidemiological evidence. These approaches are so far apart. A phrase comes to mind "They appear to be playing their own game and making up the rules as they go along". This analogy appears to be helpful. These two approaches are like two different games.

ICNIRP is playing its own game and setting its own rules. It is the game that is played by national authorities which, as a team, they feel very comfortable with it. The name of the team is "The Consensus of Science". However, it involves quite a small and very select team which includes national experts who come from national authorities who subscribe to the rules of the ICNIRP game. In the ICNIRP game the first rule is that there is only a tissue heating effect from RF/MW exposure. As a consequence of this rule, in the ICNIRP game, all other biological effects are not real and any epidemiological study that shows an effect with nonthermal exposure, must be faulty and will be rejected. In other words, if you break this rule you are out of the game. In this game it is fine to change the rules about acceptable significant, what is evidence, and criteria for how a biological effect is established. In this game a study does not provide evidence until it has been exactly

replicated. You set up 13 criteria which must be achieved for an experiment to be reliable, for example Meltz (1993). If even one criteria is breached then you can reject the findings. Similarly the ICNIRP team uses the Bradford-Hill Criteria to criticize epidemiological studies. One criticism, valid or not, is sufficient to reject a whole study.

In the Public Health Protection Game the first rule is that public health protection standards are based on public health studies, i.e. epidemiology. Epidemiological evidence is sufficient to set standards where there are dose-response relationships or when studies have shown significant adverse effects and the lowest estimate of exposure is reasonable, and then a safety factor is applied to deal with the uncertainty. Avoidance action and experiment are a vital part of this game.

Avoidance action is taken long before scientific proof of cause and effect is reached. This is because it is recognized that many disease agents cause sickness and death years or even decades after the initial exposure. Unnecessary delay is avoided and action is taken to protect public health, once the evidence is judged sufficient under the circumstances. A reversible adverse effect can be treated differently than permanent damage that hastens disease and death, such as miscarriage, congenital malformation, brain damage or cancer. The Bradford-Hill viewpoints inform this decision-making, Hill (1965).

6. Non-Thermal Biological Mechanisms

Veteran EMR biological researchers Dr Ross Adey, Dr Carl Blackman, and Dr Alan Frey and eminent epidemiologist, the late Dr John Goldsmith, cite sound evidence which totally refutes the claim that there are no established non-thermal biological mechanisms.

6.1 Dr Ross Adey directly challenges the thermal view:

Dr W. Ross Adey is one of the world's most respected veteran EMR researchers. His pioneering work on neuroscience gives deep insights into biological functions and processes. The following is the abstract from his paper "Frequency and Power Windowing in Tissue Interactions with Weak Electromagnetic Fields": (Proc. IEEE 1980)

"Abstract: Effects of non-ionizing electromagnetic (EM) fields that raise tissue temperature in general differ very little from effects of hyperthermia induced by other means. However, fields raising tissue temperature orders of magnitude less than 0.1°C may result in major physiological changes not attributable to raised temperature *per se*.

These weak fields have been observed to produce chemical, physiological, and behavioral changes only within windows in frequency and incident energy. For brain tissue, a maximum sensitivity occurs between 6 and 20 Hz. Two different intensity windows have been seen, one for ELF tissue gradients around 10^{-7} V/m, and one for amplitude modulated RF and microwave gradients around 10^{-1} V/m. The former is the level associated with navigation and prey detection in marine vertebrates and with the control of human

biological rhythms; the latter is the level of the electroencephalogram (EEG) in the brain tissue.

Coupling to living cells appears to require *amplifying* mechanisms that may be based on non-equilibrium processes, with long-range resonant molecular interactions. The *cooperative* processes are now recognized as important in immune and hormonal responses, as well as in nerve excitation. Polyanionic proteinaceous material forming a sheet on the cell membrane surfaces appears to be the site of detection of these weak molecular and neuroelectric stimuli."

Professor Adey succinctly summarizes EMR research at that time. He does not claim, in the body of the paper, that the two observed intensity windows are the only intensity windows, but that these are intensity windows that have repeatedly been shown to have significant effects.

In his conclusion Dr Adey directly challenges the thermal view.

"Too many physicists and engineers cling desperately to the thermal models as the alpha and omega of bioeffects from non-ionizing radiofrequency fields, shunning the exquisite beauty of long-range molecular interactions and resonant processes in biological macromolecules."

In Adey (1993) intercellular communications are described as "whispering between cells". Dr Adey notes new work which involves free radicals:

"that may also participate in highly cooperative detection of weak magnetic fields, 'even at levels below thermal (kT) noise'."

The key role of resonance and tuning is addressed.

"In recent studies (Grundler and Kaiser (1992)), they noted that the sharpness of the tuning increases as the intensity of the imposed field decreases; but the tuning peak occurs at the same frequency when the field intensity is progressively reduced. Moreover, clear responses occur with incident fields as weak as 5 picowatts/cm²."

A 5 pW/cm² signal is billions of times below the ICNIRP guideline for GHz signals. The studies cited by Dr Adey show the fundamental biological role of frequencies, tuning and resonance. Kaczmarek and Adey (1973) showed that weak oscillating electric gradients, no larger than the EEG (50-100 mV/cm), increase efflux of calcium ions and GABA from cat cerebral cortex by almost 20%. Cellular calcium ions play many vital roles in cell growth and development regulation. Hence the ability of EMR to induce changes in cellular calcium ions is fundamentally important in assessing the biological mechanisms which contribute to adverse health effects.

6.2 Calcium ion (Ca²⁺) efflux:

Adey (1979) contains evidence of other windows for ELF induced Ca²⁺ efflux in chick and cat brains, e.g. 5, 10, 56 and 100 V/m (Figure 8), and other microwave intensity windows for Ca²⁺ influx and efflux. The field intensity and modulation frequency were shown to be important parameters in EMR causing Ca²⁺ efflux.

Figure 8: The effects of extremely low frequency fields on $^{45}\text{Ca}^{2+}$ efflux from chick forebrain, for ELF fields of 5, 10, 56 and 100 V/m. *: $p < 0.05$; **: $p < 0.01$, Bawin and Adey (1976).

Figure 9 shows significant Ca^{2+} efflux with exposure intensity at 0.05, 0.1 and 1 mW/cm^2 , but not at 2 and 5 mW/cm^2 with a 450 MHz carrier. Particular higher exposures do not have the same significant effects as lower specific exposures, indicating that this is a non-thermal mechanism.

Figure 9: Effects of changing intensity of 450 MHz field amplitude modulated 16 Hz as efflux of $^{45}\text{Ca}^{2+}$ from chick cerebral hemispheres. Cross-hatched bars show levels of efflux exposed specimens in relation to control specimens (stripped bars) tested simultaneously in the same experiments. Variance is shown as SEMs **, $p < 0.05$.

Adey (1979) reviews a large body of research on the Neurophysiologic effects of RF/MW radiation. This included the human biometeorological research on circadian rhythms in human subjects isolated from sunlight and EMR; their own work on altered monkey behaviour with a tissue gradient of 10^{-7} V/m and other animal behaviour experiments. It also covered cellular evidence including Ca^{2+} flux experiments on cats and chick brains.

These show that ionic changes in amplitude modulated RF/MW fields are much more related to modulation frequency than intensity of signal. Often higher effects are seen at lower exposure intensities than some higher intensities - in windows.

It was established very early on that an ELF signal carried on a RF carrier produced altered cellular Ca^{2+} fluxes, as the ELF signal on its own, but with a very much higher induced tissue electric field gradient, Bawin and Adey (1976), Figure 10.

Significant effects occur in fields that are too low to produce any detectable thermal effects. In great frustration at the intransigence of the position held by scientists who doggedly claim that there is only evidence of thermal effects. Professor Adey concludes:

"Faced with the overwhelming complexity of the brain as a tissue and as the organ of the mind, physical scientists and medical researchers alike have all too often retreated shamelessly into classicisms and the argots of their respective trades. Too many physicists and engineers cling desperately to thermal models as the alpha and omega of bioeffects from non-ionizing radiofrequency fields, shunning the exquisite beauty of long-range molecular interactions and resonant processes in biological macromolecules."

"True science can never be a popularity contest. The time has surely come when we should place these scholasticisms of another age in a proper context, counting ourselves thrice blessed at the prospect that through the use of non-ionizing radiofrequency radiation as a research tool, the intrinsic organization of the brain tissue, the subtleties of neuroendocrine phenomena and the broad sweep of immunological interactions may at last be understood in terms of transductive coupling at the molecular level."

Figure 10: Relative Ca^{2+} efflux (positive and negative) from isolated chick cerebral hemisphere exposed to (A) weak RF field (147 MHz, 0.8 mW/cm², 56 V/m in air), amplitude modulated at low frequencies (abscissa) (Bawin et al. (1975) and (B) ELF electric field (56 V/m in air) over the same modulation frequency range, Adey (1988). The tissue gradients differ by 10^6 between A and B.

Dr Adey was basing his insights on a fascination with discovering how neurological tissue operated and how it was altered in extremely low level RF/MW and ELF fields. The current world leader in Ca^{2+} efflux research is Dr Carl Blackman of the U.S.E.P.A. Blackman has replicated and significantly extended the studies carried out by Dr Adey's group and other groups. Dr Blackman has produced over 2 dozen peer-reviewed publications in this area, including several major reviews.

Blackman et al. (1989) identified multiple power density windows for Ca^{2+} efflux, using a 50 MHz carrier modulated at 16 Hz. Their results, using units of mW/cm^2 , are summarized as follows:

No change	0.75	2.30	4.50	5.85	7.08	8.19	8.66	10.6	14.7
Enhanced efflux	1.75	3.85	5.57	6.82	7.65	7.77	8.82		

The intensity window data was considered as an example of non-linear dynamics because there appears to be no progressive decline in the magnitude of the effects at low exposure intensities. This data is consistent with a fractal process with a non-integer dimension which is approximately 1.4, Blackman et al. (1989).

The lowest published RF intensity that has been documented to produce significant Ca^{2+} efflux is 0.00015 W/kg from Schwartz et al. (1990). They used frog hearts, exposed for 30 mins, to a 16Hz modulated 240 MHz RF signal. This has an exposure intensity of about $0.4 \mu\text{W}/\text{cm}^2$.

Blackman's group confirmed and significantly extended the "windows" concept of Ca^{2+} efflux, as well as aspects of homeostasis, involving tissue temperature for example. Figure 11 shows how modulation frequencies out to 510 Hz produce significant Ca^{2+} efflux at some frequencies, but not at other frequencies on either side.

Figure 11: Effect of $15 \text{ V}_{\text{rms}}/\text{m}$ electromagnetic fields on the efflux of Ca^{2+} from chicken brain tissue as a function of modulation frequency, Blackman et al. (1988). The solid bars show significant alteration, $p < 0.05$.

Blackman et al. (1990) showed the importance of the local static magnetic field and Blackman et al. (1991) showed that Ca^{2+} efflux occurred for tissue temperatures of 36 and 27 °C and not at 35 and 38°C. They comment that these could be very good reasons why experimental outcomes have been difficult to confirm in some laboratories.

After reviewing the many studies in the published literature on EMR induced Ca^{2+} efflux. Blackman (1990) concludes:

"Taken together, the evidence overwhelmingly indicates that electric and magnetic fields can alter normal calcium ion homeostasis and lead to changes in the response of biological systems to their environment".

Blackman (1990) concludes that calcium ion efflux/influx is an established biological effect of EMR exposure. The variable nature of the response, as indicated by complex exposure 'windows', indicates that EMR acts like chemicals (plural) rather than acting like a single chemical Blackman (1998). Because modulation frequencies are critically involved, and low intensity exposures are observed under some circumstances to produce greater effects than some higher exposure conditions, resonant interactive processes are indicated and heating is definitely not involved except to establish a homeostatic range.

6.3 Health implications of induced alterations in calcium ion homeostasis:

Induced alteration of cellular calcium ions:

- of brain cells is associated with behavioural and reaction time changes and associated EEG alterations, Bawin et al. (1978);
- of the pineal gland reduces the nocturnal production of melatonin (which increases the cell damage throughout the body, reduces the integrity and competence of the immune system, and hence increases the incidence of cancer and immune system related disease and degenerative diseases of the brain, Reiter (1994) and Walieczech (1992);
- of lymphocytes reduced the competence of the immune system making the subject more vulnerable to allergens, toxins and viruses, and to leukaemia; and
- of damaged cells alters the ratio of surviving neoplastically transformed cells and those programmed to self destruct (apoptosis), Balcer-Kubiczek (1995).

The neurological role of Ca^{2+} is well described and documented by Dr Adey. A university text on the molecular biology of the cell, Alberts et al. (1994), documents many cellular processes which depend on Ca^{2+} , including cell-cell adhesion, gap junction gating, intracellular mediation, cyclic AMP and ATPase processes, and signal transduction as a second messenger. Ca^{2+} mediate process in the hyppocampus involved with learning. They also mediate apoptosis. Chemical carcinogens, such as the tumor promoting phorbol esters, for example TPA, act by elevating intracellular calcium, Balcer-Kubiczek (1995).

Cells have voltage-gated Ca^{2+} channels in the cell membrane to allow the influx and efflux of calcium ions in order to regulate cellular processes, Adey (1993).

Ca^{2+} mediate gene expression processes, development and plasticity of the nervous system, activity-dependent cell survival, modulation of synaptic strength and calcium mediated cell death, Ghosh and Greenburg (1992). They are involved in the Ca^{2+} -cAMP signal transduction process that mediates several cellular functions, including melatonin production in pinealocyte, Zurawska and Nowak (1992). Li et al. (1999) showed that 50 Hz fields in TPA treated cells produce a significant dose-response decrease in gap junction communication with magnetic fields of 0.2, 0.4 and 0.8 mT.

Neurological effects intimately involve Ca^{2+} as shown originally by Dr Adey's group. This includes mediation of sodium ion activity in the brain, Charpentier and Kado (1999). Walleczek (1992) reviewed the roles of Ca^{2+} in the immune system including regulation of leukocytes, lymphocytes and Natural Killer Cells, mainly through signal transduction processes. Through their synergistic activity with cAMP, Ca^{2+} mediate some key hormones including luteinizing hormone, testosterone, prolactin and Growth Hormone, Veldhuis et al. (1984), Kotwicka and Warchol (1998), Rillema (1980), Vacher et al. (1994), Ilondo et al. (1994), Ray and Wallis (1982), and Davis et al. (1987).

Cardiac regulation occurs using calcium ion signaling, Reuter (1987) and Ugarte et al. (1998). Takahashi et al. (1992) found that altered expression of Ca^{2+} -dependent genes are involved in end-stage heart failure.

Calcium ion influx is critical to mitogen action, Hadden (1987). In this process Ca^{2+} acts directly and indirectly through its action on calmodulin and protein kinase C to the activation of a number of enzymatic processes. The tumor suppresser gene p53 is regulated by Ca^{2+} , Metcalf et al. (1999). Ca^{2+} also regulates the transcription of the c-fos proto oncogene, Montminy et al. (1990), Thompson et al. (1995) and Werlen et al. (1993). One of the key roles on Ca^{2+} in the carcinogenic process is outlined by Fanelli et al. (1999) who showed a dose response relationship for Ca^{2+} influx over a static magnetic field range from 60 to 600 μT . This Ca^{2+} influx was observed to inhibit apoptosis. Fanelli et al. stated that magnetic fields thus might interfere with human health by altering/restoring the equilibrium between cell death and proliferation. Indeed, they conclude, the rescue of damaged cells may be the mechanism explaining why magnetic fields that are not mutagenic per se are often able to increase mutation and tumor frequencies.

Hence EMR's proven ability to induce calcium ion fluxes and to significantly alter cellular calcium in homeostasis is a direct biological mechanism for all of the biological effects associated with EMR exposure. Taken together, this provides an established biological mechanism for genetic damage, reproductive problems, cardiac disease, cancer and increased risk of viral and bacterial infection. The key cancer mechanisms involve reduced melatonin, DNA strand breaks, chromosome aberrations, altered proto oncogene expression and impairment of the immune system. These have all been linked to EMR exposure across the EMR spectrum from ELF to RF/MW.

Ca^{2+} have been implicated in essentially every step of the transductive coupling of neurotransmitter substances in effects of every step of the immunological reactions and every step of the coupling of hormonal binding at the membrane surfaces to cellular mechanisms, Adey (1979). Ca^{2+} efflux is the initial biological mechanism for almost all of

the observed significant adverse health effects of EMR exposure, including neurological, cardiac, reproductive and cancer effects.

Biochemists have now confirmed that RF/MW alters signal transduction, (e.g. Luben (1995), Byus (1994)), alters melatonin and damages the immune system, as will be shown below.

6.4 Dr Alan Frey directly challenges the RF Thermal view.

Dr Frey, an eminent U.S. biologist, has several decades of EMR research including being the discoverer of "Microwave Hearing". In the introductory chapter of a book that he edited, Dr Frey describes the historical tendency to use the toxicological model that treats EMR as an external agent, Frey (1995). He then refers to Burke and others who have made it clear that "our frame of reference determines what we look at and how we look. And as a consequence, this determines what we find." This is demonstrably true for the ICNIRP assessors. Dr Frey then states "Theory and data show that this is the wrong model. Electromagnetic fields are not a foreign substance to living beings, like lead or cyanide."

"To model how em fields affect living beings, one might compare them to the radio we use to listen to music. The em signal the radio picks up and transduces into the sound of music is almost unmeasurably weak. At the same time there are, in total, strong em fields impinging on the radio. We don't notice the stronger em signals because they are not the appropriate frequency or modulation. Thus they don't disturb the music we hear. However, if you impose on the radio an appropriately tuned em field or harmonic, even if it is very weak, it will interfere with the music. Similarly, if we impose a very weak em signal on a living being, it has the possibility of interfering with normal function if it is properly tuned. This is the model that much biological data and theory tell us to use, not a toxicology model."

Wever (1974) and Konig (1974) proved that human brains are tuned to detect and use the Schumann Resonances that have an intensity of the vertical electric field component of about 0.1 pW/cm^2 . This is 10 billion (10^{10}) times lower than the ICNIRP guideline for low frequency signals. Ahissar et al. (1997) demonstrated that mammals brains contain biochemical phase-locked loop circuits to detect the phase difference between incoming ELF signals in the same manner as FM radio receivers.

6.5 EMR Reduces Melatonin in Animals and People

Light-at-night and electromagnetic radiation, are proven to reduce melatonin and hence pose significant adverse health effects. The evidence for EMR is summarized here. Rosen, Barber and Lyle (1998) state that seven different laboratories have reported suppression of nighttime rise in pineal melatonin production in laboratory animals. They show that a $50 \text{ } \mu\text{T}$, 60 Hz field with a $0.06 \text{ } \mu\text{T}$ DC field, over 10 experiments, averages a 46% reduction in melatonin production from pinealocytes. Stark et al. (1997) observed a significant increase in salivary melatonin in a group of 5 cows when the short-wave radio transmitter at Schwarzenberg, Switzerland, was turned off for three days, compared to 5 cows who had much lower RF exposure. Hence there are now nine independent observations of melatonin reduction in animals from ELF and RF exposure.

Ten studies show that RF/MW exposure and ELF exposure can reduce pineal melatonin production in people. Evidence that EMR reduced melatonin in human beings commenced with Wang (1989) who found that workers who were more highly exposed to RF/MW had a dose-response increase in serotonin, and hence indicates a reduction in melatonin. Nine studies have observed significant EMR associated melatonin reduction in humans. They involve a wide range of exposure situations, including 50/60 Hz fields, Wilson et al. (1990), Graham et al. (1994), Wood et al. (1998), Karasek et al. (1998), and Burch et al. (1997, 1998), 16.7 Hz fields, Pfluger et al. (1996), VDTs Arnetz et al. (1996), a combination of 60 Hz fields and cell phone use, Burch et al. (1997), and a combination of occupational 60Hz exposure and increased geomagnetic activity around 30nT, Burch et al. (1999). The tenth human melatonin reduction study is from RF exposure as reported during the shutting down process of the Schwarzenburg shortwave radio tower, Professor Theo Abelin (seminar and pers.comm.).

Hence it is established from multiple, independent studies, that EMR from ELF to RF/MW reduces melatonin in animals and human beings.

Professor Russell Reiter, one of the world's leading medical researchers into the effects of melatonin, summarizes melatonin's roles, Reiter and Robinson (1995), as being:

- Vital for healthy sleep, including lowering the body temperature, and assisting in maintaining health sleep states.
- Reduces cholesterol, with consequent reductions in risk of atherosclerosis and coronary heart disease.
- Reduces blood pressure and the tendency for blood clots, and hence reduces the risk of strokes.
- Scavenger of free radicals. This, along with the above factors, reduces the risk of heart attack, cancer, viral replication. Melatonin plays a vital free radical scavenging role in the brain where, because it is high in iron, has a high production rate of hydroxyl radicals (OH•). Free radical damage is now known to play a formative role in most brain disorders, including Alzheimer's disease, Lou Gehrig's disease, multiple sclerosis and Parkinson's disease. While the Blood Brain Barrier (BBB) denies access to most free radical scavengers, melatonin has free access.
- Enhances the effectiveness of the immune system. Specifically enhancing the T-cells, i.e. the T-helper cells and the T-killer cells. T-helper cells have a receptor for melatonin. When melatonin is received a cascade of events is set in motion including stimulation of Interleukin-4 (IL-4) which then stimulates natural killer cells (NK), B-cells, IgA, phagocytes and T-Cytotoxic cells. The NK cells specialize in attacking cancer cells and virus infected cells.

In Professor Reiter's book, published in 1995, he describes the evidence that EMR/EMF does reduce melatonin as a "Smoking Gun" level of proof. That is, there is considerable scientific evidence but at that time it wasn't sufficient for scientific proof. By considering more recent information, and the extensive results of biometeorological research, and linking the melatonin research to the calcium ion research, the level of proof can be seen as causal. The multiple observations of melatonin reduction in EMR exposed populations

means that EMR exposure increases the incidence of all of the conditions identified by Reiter and Robinson above, including immune system, cancer, neurological and cardiac effects. Epidemiological evidence of exposed workers and residential populations confirms that these adverse health effects do occur.

6.6 Human Biometeorology:

Dr Ross Adey refers to the work of Wever and Konig in Germany in the 1960's and 70's. The work was carried out at the Munich Technical University and the Max Planck Institute. Wever and his colleagues constructed two isolation rooms to remove all daily time signals. One, Room 2, as also surrounded by a Faraday Cage to exclude electromagnetic signals, Wever (1974). The results included the fact that those in the Faraday Cage shielded room, identical to the other room in all other respects, had significantly longer circadian rhythms ($p < 0.01$).

In addition, a significant proportion of the Faraday Cage group “desynchronized” while none of the other group did ($p < 0.001$). This involved rapid lengthening of the circadian period from around 26-27 hours to 30 - 36 hours, Figure 12.

Figure 12: Free-running circadian rhythm of a subject living under strict isolation from environmental time cues. During the first and third section protected from natural and artificial electromagnetic fields, during the second and fourth sections (shaded area) under the influence of a continuously operating 10 Hz electric field of 2.5 V/m, Wever (1974).

Long-term isolation experiments at the Max Planck Institute proved that removing sunshine led to significantly longer mean circadian periods. Also shielding subjects from natural and artificial EMR further significantly extends mean circadian periods. Around 30 % of subjects desynchronized. When a weak 10 Hz signal was secretly introduced the desynchronization was removed, Figure 5. This proved the role of the Schumann Resonances that act with sunshine as a Zeitgeber.

From the results of the experiments involving human subjects, their reaction times and altered circadian rhythm, the German researchers from the Max Planck Institute conclude:

“Thus, it has been proven at a high statistical level that the artificial electric 10 cps field diminishes the tendency towards internal desynchronization, as does the natural field.”

The desynchronization was removed through the application of a 10 Hz signal with a peak to peak field strength of 2.5 V/m. This is equivalent to $0.83 \mu\text{W}/\text{cm}^2$. The signal the Faraday cage had removed, which was replaced by this artificial signal, was the Schumann Oscillation which has a field intensity of about $0.1 \text{ pW}/\text{cm}^2$. Hence the desynchronization was caused by the removal of a $0.1 \text{ pW}/\text{cm}^2$ signal. Wever (1974) concludes that their research gives:

“Significant proof that electromagnetic fields in the ELF range influence the human circadian rhythms and therefore human beings.”

The plausible biological mechanism involving local Schumann Resonances (Type I) and sferics (Type II) signals, was proposed by König (1974). He noted the strong similarity between the frequencies of the Schumann Oscillation and the alpha band of the human EEG, see the Figure 13 below.

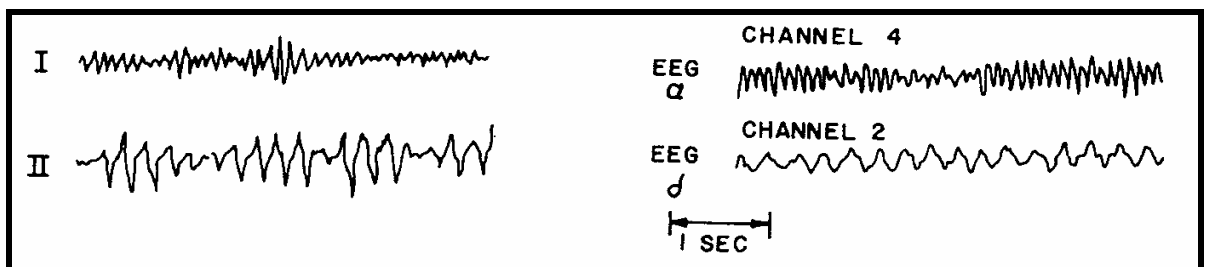

Figure 13: Electric fields from I, the Schumann-Resonance, II, Local fields of about 3 Hz and the α (10 Hz) and δ (3 Hz) human EEG channels, König (1974).

A resonant interaction is clearly feasible. Removing the Schumann Oscillation from some individuals, removes part of their circadian control. The Type II signals on the left are naturally occurring, locally sourced ELF fields centred around 3 Hz, close to the delta EEG band. König (1974) showed that people's reaction time significantly slows in the presence of Type I signals and sped up when Type II signals were dominant, Figures 14 and 15.

Signals of the Type II occurred during 10 occasions during the August-September period. Figure 8 shows the inter-relation for the change in reaction time relative to the onset of Type II signals at time n hr. In the hour and a half after the onset of Type II signals the reaction times (involving between 2000 and 3000 people), are well above average.

Figure 14: The solid line shows the reaction times of 4500 people per point, over the day in September 1953 in Munich, compared with (dashed line) the Type I (10 Hz) signals field intensity.

Figure 15: The speeding up of the reaction time of people in the 60 to 90 minutes following the onset of 3 Hz signals, from the Traffic Exhibition in Munich in 1953.

At the same time that the Germans were publishing their biometeorological results showing that human being's reaction times vary with extremely low intensity naturally

occurring and varying electromagnetic fields in the ELF part of the spectrum, Professor Ross Adey and Dr Susan Bawin were showing that altered human reaction times in ELF modulated microwave fields was associated with altered EEG and calcium ion efflux from the brain cells.

Hence the U.S. and German research jointly confirm both the effect and the mechanism, extended and strongly confirmed by Cherry (2002). Human brains detect oscillating EMR signals, the Schumann Resonance (SR) signal, at very low intensities (0.1pW/cm^2) through resonant absorption interactions. This results in altered reaction times and circadian rhythms through induced changes in cellular calcium ions and reduced melatonin. Cherry (2002) shows that the modulation of the SR signal by Solar Activity, modulates cancer, cardiac, reproductive and neurological disease and mortality rates in human populations through the melatonin mechanism. These two biological effects and serious human health effects are shown to occur over a wide range of exposure conditions from ELF to RF/MW and at apparently very low exposure intensities, that are about a million times higher than the SR signal.

6.7 EMR should be treated as multiple “Chemicals”:

At the Scientific Workshop on Biological Effects of Electromagnetic Radiation in Vienna, October 1998, Dr Carl Blackman, U.S. Environmental Protection Agency, presented the results of 30 years of research into cellular calcium ion efflux and influx which is induced by pulsed and modulated EMR. The work is well characterized as occurring within particular windows of intensity of signal ($\mu\text{W/cm}^2$), modulation frequency, carrier frequency and temperature range. Statistically significant efflux or influx of calcium ions from exposed cells has been repeatedly observed for particular combinations of intensity, carrier frequency, modulation frequency and temperature, and not found at a nearby frequency intensity. These “windows” of effect have been found down to extremely low field intensities and are not found at some high but still athermal exposure levels.

Cellular calcium ion alteration in the presence of time varying electromagnetic fields is an established biological effect of EMR exposure. However, the “windowing” nature of this particular biological effect means, according to Dr Blackman, that **EMR must be considered as chemicals (plural) and not just a single chemical.**

Since alteration of cellular calcium ions concentration leads to many different health effects, and since many other biological changes have been identified, it is inappropriate to limit consideration of RF/MW exposure to single adverse health effects.

EMR exposes the whole human body and not a single target organ. Each organ has a different cellular structure which relies to a greater or lesser extent in electric and magnetic factors and forces for its growth and control. The brain, central nervous system and muscles, including the heart, make much stronger use of electrical signals than bones for example. However, every cell has an electric potential across its membrane and uses ions, such as calcium ions (Ca^{2+}), sodium ions and potassium ions. Receptors on cells are negatively charged and ions and neurotransmitters which initiate signal transduction are positively charged. DNA is negatively charged and the protein which is bound to it is positively charged.

Hence, every cell can interact with EMR and EMR can alter the growth regulation factors through alteration of the ionic concentration within the cells and in the intracellular fluid.

Some higher functioning organs, especially the brain and CNS, are dependent on EMR for normal operation and have been shown to be altered by externally applied EMR, with consequent behaviour and neurological performance change, Bawin et al. (1976).

Because the whole body is exposed to RF/MW radiation, and since the brain and central nervous systems are electrically sensitive and active, it is not surprising that the most frequent adverse health effects identified in epidemiological studies are leukaemia and brain tumour. Leukaemia is a disease of the blood and bone marrow, whole body organs.

The ICNIRP approach, which at best can be seen as treating EMR as a single chemical, uses the observation that an effect shown in one laboratory or health study, but is not found in another when different frequencies, modulation frequencies, intensities and populations and effects are involved, as a reason to ignore the effects shown. By moving to the concept that EMR has different effects in different combinations of exposure parameters, much more accurate and appropriate interpretation of the scientific data is possible and more accurate.

7. Bioelectromagnetic Principles:

A more appropriate scientific approach than that taken by ICNIRP is one which recognizes some fundamental principles concerning the nature of biological systems and their use and interaction with EMR.

7.1 Bioelectromagnetic Principle 1:

EMR is intrinsic to our bodies.

Intrinsic EMR signals are used for timing regulation at all levels, from seasonal and circadian rhythms, heart beat, cell ion oscillations, cell cycle timing, Adey (1980), Becker and Seldon (1985), Frey (1992),.

7.2 Bioelectromagnetic Principle 2:

Our brains are the most electrically active organs in our bodies.

Interference with timing leads to arrhythmia of brain, neurological effects and diseases and brain tumours. The brain's electro-sensitivity results in modulation of the melatonin serotonin cycle, which leads to a very wide range of extremely serious health effects.

7.2.1 Supporting Evidence:

König (1974) and Wever (1974) proved that human brains detect local lightning signals and the globally radiated Schumann Resonance signals by showing that these signals alter human reaction times and regulate human circadian rhythms, at intensities around 0.1 pW/cm^2 , Polk (1982). This work is indicative of a resonant absorption interaction between the Schumann Resonance Spectrum and human brain waves (EEG-rhythms), Cherry (2002).

Shandala et al. (1979) show that microwaves significantly altered the EEG of animals, Von Klitzing (1995) shows that a GSM signal alters the EEG of human volunteers and Mann and Roschke (1996) show sleep disturbance and EEG change from sleeping next to a cell phone. Mild et al. show that cell phone users exhibit a significant dose response increase in neurological symptoms, including dizziness, memory loss, loss of concentration and headaches.

Ninety-six studies identify increases in brain tumours with EMR exposures across the spectrum; 45 are statistically significant and 12 have significant dose-response relationships, Cherry (2002a).

Several epidemiological studies show significant increases in neurological effects and diseases in residential and occupational EMR exposures, Amyotrophic Lateral Sclerosis (ALS) and Parkinsonism, Deapen and Henderson (1986); Suicide, Baris and Armstrong (1990), Perry et al. (1991); Alzheimer's Disease, Sobel et al. (1995, 1996); Clinical Depression, Verkasalo et al. (1997); Psychological symptoms, Beale et al. (1997); and ALS, Savitz et al. (1998). Beale et al. found significant dose-response relationships for several symptoms including depression and anxiety and Johansen et al. (1999) for Multiple Sclerosis and Savitz et al. (1998) for ALS.

7.2.2 Alzheimer's disease:

Sobel et al. (1996) found that workers in industries with likely electromagnetic field exposure have a very significant ($p=0.006$) increase in incidence of Alzheimer's disease, OR = 3.93, 95% CI: 1.5-10.6. For males the adjusted odds ratio was 4.9, 95% CI: 1.3-7.9, $p=0.01$, and for females, OR = 3.40, 95% CI: 0.8-16.0, $p = 0.01$. They note that:

"These results are consistent with previous findings regarding the hypothesis that electromagnetic field exposure is etiologically associated with the occurrence of AD."

Sobel and Davanipour (1996) outline the etiological process they hypothesize by which EMR produces Alzheimer's disease.

- The first step involves EMR exposure upsetting the cellular calcium ion homeostasis through calcium ion efflux from cells increasing the intracellular calcium ion concentrations. This cleaves the amyloid precursor protein to produce soluble amyloid beta ($sA\beta$).
- $sA\beta$ is quickly secreted from cells after production, increasing the levels of $sA\beta$ in the blood stream. $sA\beta$ then binds to Apolipoprotein E and apolipoprotein J to be transported to and across the Blood Brain Barrier.
- Over time, when sufficient $sA\beta$ have been transported to the brain, a cascade of further events lead to the formation of insoluble neurotoxic β pleated sheets of amyloid fibril, senile plaques, and eventually AD.

The biological mechanism for EMR to cause Alzheimer's disease is well advanced and entirely plausible, commencing with calcium ion efflux.

7.2.3 Sleep disturbance:

Thus the German work in the 1960's and 1970's established that naturally occurring EMR and EMR at extremely low levels influenced and altered sleep, circadian rhythm and reaction times. In the 1990's German work showed the cell phones alter the human EEG and interfere with REM sleep, Von Klitzing (1995) and Mann and Roschke (1996). Impairment of REM sleep is associated with memory and learning difficulties. The Swiss research (Altpeter et al. (1995) and Abelin (1998) - The Schwarzenburg Study) found a causal relationship between sleep disturbance and subsequent chronic fatigue, and short-wave radio exposures at extremely low mean levels.

When the transmitter was turned off for three days, sleep quality improved in all three groups being studied. This included Group C, the most remote and least exposed group. Their 24 hour mean and median exposure was measured as 0.1 mA/m which equates to 0.4 nW/cm². Hence the removal of RF radiation of 0.4 nW/cm² significantly improves the sleep quality in a monitored group, showing that this intensity of RF radiation causes significant deterioration in sleep quality in populations.

Salival melatonin was measured in cows in the Schwarzenburg study in 5 'exposed' cows and 5 'unexposed' cows. The exposed cows had lower mean melatonin levels but the difference was not statistically significant because the sample was too small. Human beings were sampled (using urine analysis). Samples were taken first thing in

the morning when melatonin levels are naturally low, instead of at the correct time soon after midnight, when melatonin levels are high and reductions are easier to detect. However, the research team noted “Persons reporting sleep disorders, however, tend to have lower melatonin levels.” When the decision was made to close down the transmitter permanently, melatonin readings were taken of a large group of residents before and after the closure. This showed a significant increase in melatonin following the closure, Professor Theo Abelin pers. Comm - seminar).

When the transmitter was off for three days the melatonin in the exposed cow herd reached their highest nocturnal peaks for that week. When the transmitter went on again, on that day the exposed cows’ melatonin was statistically significantly lower than the unexposed cows.

The causal relationship between RF radiation exposure and deterioration in sleep quality is identified through a significant dose response relationship ($p < 0.001$), improvements in sleep quality which changing the direction of the beams and turning the transmitter off, and reduced melatonin as the biological mechanism.

The causal relationship with human sleep disturbance is strong evidence of a significant neurological effect of RF radiation on people, associated with mean exposures down to 0.4 nW/cm^2 . Hence, it is highly likely that cell phone users, with brain exposures many millions of times higher than the Schwarzenburg exposure levels, will experience significant neurological effects.

7.2.4 Neurological effects of cell phone usage:

In 1998 Mild et al. (1998) survey around 11,000 cell phone users in Norway and Sweden, Figure 16. They found significant dose response relationships for a number of crucial symptoms that had been clinically described and associated with cell phone use by Hocking (1998).

The symptoms include dizziness, a feeling of discomfort, difficulty with concentration, Memory Loss, Fatigue, Headache, Burning Skin and tinglingness and tightness of the skin near the phone. The symptoms were consistent across analogue and digital (GSM) phone users. A dominant physical symptom was a sensation of warmth on the ear and behind the ear. These is not a sensation which is experienced with a conventional telephone but are unique to the cell phone which exposes the user’s head to moderate to high intensities of microwaves. It was significant that the neurological symptoms were highly correlated to the warm sensations. The symptoms are consistent with the Schwarzenburg symptoms. The headache symptoms were found with microwave exposure during “microwave hearing” experiments, Frey (1998).

Figure 16: The prevalence of symptoms with various categories of calling times/day, A. Norway, B. Sweden, Mild et al. (1998).

7.3 Bioelectromagnetic Principle 3:

Our hearts are electrically sensitive.

7.3.1 Supporting Evidence:

Hearts use EMR signals that are detectable by the ECG. An electric pulse produces a cascade of calcium ions that causes the heart muscle to contract and produces a heart beat.

7.3.2 Heart Disease:

Satre, Cook and Graham (1998) observed significantly reduced heart rate variability (HRV) in volunteers sleeping in 60Hz fields. Extrinsic EMR signals interfere with hearts

and cause heart disease and death. Bortkiewicz et al. (1995, 1996, 1997) and Szmigielski et al. (1998) found that RF exposure altered heart rate variability and blood pressure. Braune et al. (1998) showed that cell phone significantly increased blood pressure. Savitz et al. (1999) found a highly significant dose response relationship for mortality from Arrhythmia related heart disease and heart attack (Acute Myocardial Infarction) for exposed electrical occupations and for individual occupations of electrician, lineman and power plant operator. This is a powerful set of epidemiological evidence showing that EMR across the spectrum increases the incidence and mortality from arrhythmia related heart disease and from heart attack.

7.3.3 Geomagnetic Activity adverse effects:

Solar activity alters the earth's geomagnetic field, electron concentrations in the ionosphere, the Q-value of the earth/ionosphere resonant cavity and intensity and frequency of the Schumann Resonance Spectrum. Since human brains and hearts are sensitive to subtle changes in environmental electromagnetic fields, evidence of correlations in cardiac functions and geomagnetic activity (GMA) would be indications of human sensitivity to very small EMR signals.

Watanabe et al. (1994) report that a 35-yr old cardiologist with a family history of heart disease, monitored himself with a blood pressure monitor at 15-min intervals for 3 years. Systolic and diastolic blood pressure and heart rate were significantly correlated with the 27.7 day solar cycle and with the geomagnetic disturbances. Pikin et al. (1998) observed that blood coagulation and platelet aggregation increased with increasing GMA. Gurfinkel et al. (1995) observed significant alterations in capillary blood flow in heart patients, correlated with GMA. These are biological effects that are risk factors for heart disease and heart attack. Many studies have found significant correlations between geomagnetic activity (GMA) and Ischemic Heart Disease and Heart Attack, for example Sitar (1990), Villoresi et al. (1998), Stoupel et al. (1996, 1999), and Oraevskii et al. (1998).

Hence blood pressure changes and reduction of heart rate variability is observed with changes in GMA, working in RF/MW environments and using a cell phone. Significant cardiac disease and death are highly correlated with subtle changes in GMA, work in electrical industries (in a dose-response manner).

7.4 Bioelectromagnetic Principle 4:

7.4.1 Cells are sensitive to EMR.

7.4.2 Supporting Evidence

Cells have a voltage across their membrane, voltage-gated ion channels through their membrane and use ions (e.g. Ca^{2+}) for many cell regulatory processes including signal transduction and gap junction gate regulation. Altering the electric field on the surface of cells alters the receptor efficiency and interferes with the voltage-gated ion channels.

Induced alteration of calcium ion homeostasis has profound and serious effects for every cell. Calcium ion efflux/influx is an established biological effect of modulated EMR exposure, Blackman (1990). Cellular calcium ions have many profound effects on cells. These include the regulation of the neurotransmitter GABA and the neurohormone melatonin, as well as being associated with DNA synthesis, chromosome aberrations,

gene transcription and protein expression, gap junction regulation, reaction times, immune system competence, heart beat regulation, apoptosis, cancer, cardiac, reproductive and neurological effects.

7.4 Bioelectromagnetic Principle 5:

7.5.1 Our whole body acts as an aerial.

Unlike many chemicals, no particular body organ is the target of an RF signal. The whole body acts as an aerial and electric current flows down through our bodies to earth. Hence RF/MW radiation impacts on every organ in our bodies, especially the wet organs.

Whole body organs such as our circulatory system and bone marrow are sensitive to the altered electric fields and the currents flowing through them, impairing our immune system and producing leukaemia, and cancer and illness throughout human bodies.

7.5.2 Supporting Evidence:

Large epidemiological studies, Robinette et al. (1980), Milham (1985, 1988), Szmigielski (1996) and Dolk et al. (1997a,b) show that diseases and cancer across many body organs is produced by RF/MW and electrical occupational EMR exposures. A Review, Elwood (1999) shows confirmation of this in its Table 3. This paper and table assisted me on behalf of the Mitcham City Council to win a case against a OneTel Cell site, in the Adelaide Planning Appeal Court. The attorney for OneTel tried to challenge my claim that the whole body was exposed to far field radiation from a cell site would cause elevated cancer rates across many by organs. In response to challenge I asked the Court to consider Elwood's paper Table 3, and consider whether multiple, independent, published studies show elevated cancer across many by the organs. The court understood and agreed with me and the appeal was withdrawn.

In all of these studies, and in many other epidemiological studies, ELF and RF/MW exposures produce significant increases in leukaemia, including residential studies with significant dose-response relationships.

7.6 Bioelectromagnetic Principle 6:

7.6.1 The brain is linked to organs and cells through EMR sensitive hormones.

Normal brain functions are communicated to the body through neurotransmitters (such as GABA and serotonin) and neurohormones (such as melatonin).

Melatonin reduction (and serotonin enhancement) by EMR has highly significant impacts on all organs and cells in our bodies, including brains, hearts and immune systems, Reiter and Robinson (1995).

7.6.2 Supporting Evidence

Natural EMR, the Schumann Resonances, are used for circadian synchronization, using phase-locked loop biochemical circuits, Ahissar et al. (1997). Artificial EMR interferes with these processes leading to desynchronization of circadian and cellular rhythms, and alteration of the timing and magnitude of the melatonin/serotonin cycle. De Seze et al.

(1999) showed that cell phone use significantly reduces the pituitary output of Thyrotropin (thyroid stimulating hormone (TSH)). TSH is a primary regulator of metabolic function.

Many animal studies and ten human studies show that EMR significantly reduces melatonin, Section 1.4.3 above. This is a plausible mechanism for cancer in all organs but especially breast cancer, immune system impairment, SIDS, heart disease and reproductive effects such as congenital malformation and miscarriage.

7.6.3 Breast Cancer:

Epidemiological studies have shown significant increases in male and female breast cancer from exposure to EMR from ELF to RF/MW, as with leukaemia and brain tumor. Table 2 summarizes the studies for Female Breast Cancer.

There is a tendency for higher rates in pre-menopausal women and those with estrogen-receptor-positive breast cancer, and for black women. Elevated incidence and significantly elevated incidence of breast cancer and breast cancer mortality has been found with electric blanket use, residence near powerlines, electrical industry employment, radio telegraph operators, and RF/MW exposure.

7.6.4 Epidemiological Studies of congenital malformation and miscarriage:

Epidemiological studies of physiotherapists and electrical occupations identify significant increases in congenital malformation and miscarriage, Kallen et al. (1982), Vaughan et al. (1984), Taskinen et al. (1990), Larsen et al. (1991), Sanjose et al. (1991), including a significant dose-response associating first trimester miscarriage to MW exposure, Ouellet-Hellstrom and Stewart (1993).

Hence metabolic functions, cancer and reproductive effects are produced and alterations occur in many other hormone regulatory functions with EMR exposure.

7.7 Bioelectromagnetic Principle 7:

7.7.1 The EMR Spectrum Principle.

The EMR spectrum should be treated as an integrated whole, with biological impacts generally increasing with increasing carrier frequency.

7.7.2 Supporting evidence:

Biological and epidemiological studies show that biological effects, including calcium ion efflux, melatonin reduction, DNA damage, and chromosome aberrations, and human health effects, including neurological, cardiac and cancer disease and death, all have been shown to occur from ELF exposure, exposures in electrical and military occupations, and with RF/MW exposure.

Biophysics shows that the Dielectric Constant varies progressively, decreasing with increasing carrier frequency, Schwan and Foster (1980). This implies, as has been observed, Bawin and Adey (1976), and calculated, Vignati and Giuliani (1997), that for a unit field exposure induced tissue electric field gradients and induced tissue currents, increase with increasing frequency.

Table 2: Epidemiological studies of Female Breast cancer associated with EMR exposure

Group	SIR/RR/OR	95%CI/(p-value)	Reference
Radio-telegraph operators	SIR=1.5		Tynes et al. (1996)
Electrical Engineers	OR = 1.73	0.92-3.29	Loomis, Savitz and Ananth (1994)
Electrical technicians	OR = 1.28	0.79-2.07	"
Telephone installers repairers, line work	OR = 2.12	1.17-4.02	"
Electrical Workers	OR = 1.38	1.04-1.89	"
Radiofrequency EMR			
Low Exp. White	OR = 1.15	p<0.05	Cantor et al. (1995)
High Exp. White	OR = 1.14	p<0.05	"
Low Exp. Black	OR = 1.23	p<0.05	"
High Exp. Black	OR = 1.34	p<0.05	"
High Exposure ELF	OR = 1.43	0.99-2.09	Coogan et al. (1996)
Pre-menopausal	OR = 1.98	1.04-3.78	"
Post-menopausal	OR = 1.38	0.82-2.17	"
Computer equipment operators, high Exp.	OR=1.80	1.04-3.12	[Trend p = 0.06]
Electric Blankets, heavy use, pre-menopausal	RR = 1.43	0.94-2.17	Vena et al. (1994)
All women	OR = 1.45	1.08-1.94	"
> 2 years of use	OR = 1.60	1.15-2.22	"
> 5 years of use	OR = 1.56	1.09-2.25	"
Positive Estrogen receptor aged 45 - 55 years.	RR = 1.12	0.78-1.43	Gammon et al. (1998)
Powerline, Sweden			
> 0.2 μ T, men	RR = 2.1	0.3-14.1	Feychting et al. (1998)
>0.2 μ T, women < 50 yr	RR = 1.8	0.7-4.4	"
>0.01 μ T, women with + estrogen receptor	RR = 1.6	0.6-4.1	"
>0.01 μ T, women with + estrogen receptor, aged < 60 years	RR = 7.4	1.0-178.1	"

This strongly indicates that if a biological or epidemiological effect is observed for ELF exposures, then that effect will be more likely to occur from RF and MW exposures. It also indicates that epidemiological assessments can be carried out by integrating ELF and RF/MW exposure studies. The uncertainties of mixed occupational exposures are significantly reduced. Vignati and Giuliani suggest, in support of this principle, that the biological effects and adverse effects observed from powerlines could well be the result of the greater biological impact of the lower field strength but measurable RF signals emitted by the powerlines.

Bawin and Adey (1976) observed significant calcium ion efflux/influx from both an ELF modulated 147 MHz signal and a pure ELF signal. Both had an ambient electric field strength of 56 V/m but the RF signal produced a tissue gradient of 10^{-1} V/cm and the ELF signal 10^{-7} V/cm. This implies that the RF field could have been a million times smaller, i.e. 5.6×10^{-5} to produce a tissue gradient of 10^{-7} V/cm that would also cause altered cellular calcium ions. This smaller RF field has an exposure intensity of 0.83 pW/cm^2 . This is of the same order as the intensity of the Schumann Resonance Spectrum during solar storms, which has been shown to have adverse health effects, for example S.I.D.S., O'Connor and Persinger (1997), Heart Attack, Oraevskii et al. (1998) and Epileptic Seizures, Ilipaev (1978).

7.8 Bioelectromagnetic Principle 8:

7.8.1 The Intrinsic Free Radical Principle.

A free radical is a chemical species possessing an unpaired electron. Oxygen free radicals are naturally generated in our bodies as part of the breathing and respiration process. Free radicals are highly reactive and can damage cellular DNA. In order to protect the DNA from the damage the protective measures and of melatonin which is a highly potent free radical scavenger. Within the cell there are many repair mechanisms, Apoptosis, and the immune system plays a vital role by identifying and attempting to eliminate damaged cells. Part of the natural ageing process is the cumulative cellular free radical damage, with the greater risk of cancer, cardiac illness, neurological disease and many other illnesses. Any external factors that reduce melatonin, reduce the health of the immune system or any of the other biochemical repair mechanisms, will enhance the natural ageing process and enhance the rates of all associated diseases. It is shown in multiple independent studies electromagnetic fields and radiation to alter melatonin and the immune system behaviour through the calcium-ion and reduced melatonin mechanisms.

7.8.2 Supporting Evidence: Free radicals

Oxygen free radicals, and other radical species, occur naturally in human bodies, Guyton and Kensler (1993). Free radicals are highly reactive and damage macromolecules such as DNA. Hence they provide a direct mechanism for causing cancer. Melatonin, as a potent free radical scavenger, and our immune system which detects and attempts to eliminate foreign cells, such as neoplastically transformed cells, are vital parts of a well developed cell repair system which is fundamental to health. Any factors or agents which reduce melatonin or impair the health of the immune system is thus carcinogenic and teratogenic.

It is the assumption of ICNIRP and those with the RF-thermal view that non-ionizing radiation cannot directly break chemical bonds and form free radicals, and therefore NIR cannot be genotoxic and cannot cause cancer and reproductive effects unless the exposure levels are high enough to cause significant tissue heating.

Several independent laboratories have observed significant genetic damage from nonthermal intensities of EMR, such as DNA strand breaks, chromosome aberrations enhanced oncogene activity. Lai and Singh (1997,1998) have shown that ELF and microwave exposures involve free radical damage of DNA-strands. Phelan et al. (1992) showed that 2.45 GHz microwaves generate oxygen free radicals in melanotic cell membranes.

7.8.3 DNA strand breakage

The first report that microwaves at non-thermal levels could produce single- and double-strand DNA breaks in *E. Coli* in solution, was Sagripanti and Swicord (1986). A much more advanced method, the “Comet Assay”, was used on brain cells extracted from rats that had been exposed while alive by Lai and Singh (1995,1996,1997). They observed single and double strand breaks in a dose-response manner, and identified the involvement of free radicals and the protective effect of melatonin.

Two other laboratories have recorded RF/MW produced significant DNA strand breaks. Verschave et al. (1994), who used a GSM cell phone signal to expose human and rat peripheral blood lymphocytes, found significantly increased strand breaks at high, but non-thermal exposure levels. Phillips et al. (1998) exposed Molt-4 T-lymphoblastoid cells to a number of cell phone technologies in the exposure range SAR = 0.0024W/kg to 0.026W/kg. At both of these exposure levels they observed significantly increased DNA damage ($p < 0.0001$) for one cell phone and decreased damage for three cell phone signals. Induced DNA repair is also a sign of DNA damage, Meltz (1995). Hence RF/MW radiation has been confirmed to enhance DNA damage under RF/MW exposure from radar-like and cell phone exposures, including an exposure level which is 3% of the ICNIRP guideline.

Four independent laboratories have also published data on ELF induced DNA strand breaks confirming that ELF EMR damages DNA strands; Lai and Singh (1997), Svedenstal et al. (1998) Phillips et al. (1998), and Ahuja et al. (1997). Lai and Singh (1997) also demonstrate the involvement of free radicals and the protective effect of melatonin. With the evidence above that EMR reduces melatonin this confirms that reduced melatonin causes higher concentrations of free radicals which produce more DNA strand breaks from EMR exposure from ELF to RF/MW frequencies. Increased DNA strand breaks will result in increased chromosome aberrations.

Multiple evidence from independent laboratories established that EMR from ELF to RF/MW causes DNA strand breaks at very low, non-thermal exposure levels.

7.8.4 Chromosome aberrations

In 1959 Heller and Teixeira-Pinto (1959) showed that non-thermal pulsed RF signals could cause complex chromosome breaks which mimicked the effect of ionizing radiation and c-mitotic chemicals. Hence significant chromosome aberrations (CA) produced by

RF/MW have been reported by eight independent groups: the staff at the U.S. Embassy in Moscow, Goldsmith (1997); Garaj-Vrhovac et al. (1990a,b, 1991, 1992, 1993); Timchenko and Ianchevskaia (1995), Balode (1996), Haider et al. (1994) and Vijayalaxmi et al. (1997). In the Mar/Apr 1999 edition of Microwave News it is reported that Drs Tice, Hook and McRee showed chromosome damage from all cell phones tested, all being statistically significant and all but one highly significant with dose-response relationships up to a factor of three increase in chromosome aberrations.

El Nahas and Oraby (1989) observed significant dose-response dependent micronuclei increase in 50 Hz exposed mice somatic cells. Elevated CA have been recorded in a number of workers in electrical occupations. In Sweden Nordenson et al. (1988) found significant CA in 400 kV-substation workers and with 50 Hz exposures to peripheral human lymphocytes, Nordenson et al. (1984) and human amniotic cells, Nordenson et al. (1994). Significant CA in human lymphocytes exposed to 50 Hz fields are also reported by Khalil and Qassem (1991), Garcia-Sagredo and Monteagudo (1991), Valjus et al. (1993) and Skyberg et al. (1993). Skyberg et al. collected their samples from high-voltage laboratory cable splicers and Valjus et al. from power linesmen.

Hence chromosome damage has been recorded from exposures across the EMR spectrum from ELF to RF/MW exposures, in plants, mammal and human cells, animals and human beings, and from many independent laboratories. This confirms that EMR does damage chromosomes and establishes EMR induced chromosome aberrations as a biological effect. For a neoplastic cell to survive it must have an altered genetic structure to store the damage and to hide this from the immune system so that NK cells do not kill the neoplasm transformed cells.

7.8.5 Gene transcripts and activity

It is shown above that EMR induces alterations in cellular calcium ion fluxes and that calcium ion fluxes mediate gene transcription and expression. Calcium ion fluxes occur in "windows" of exposure parameter combinations. Two studies associate EMR exposure alteration of gene transcription with exposure windows. Litovitz et al. (1990) identified amplitude (intensity) windows, and Wei et al. (1990) frequency windows in the range 15 to 150 Hz. They observed a peak effect in c-myc gene transcription at 45 Hz. Liburdy et al. (1993) show that c-myc induction occurs in a direct sequence from calcium ion influx. Increased c-myc gene transcripts by 50/60 Hz fields has also been observed, Goodman et al. (1989, 1992) and Lin et al. (1994). Phillips et al. (1992, 1993) observed time-dependent changes in the transcription of c-fos, c-jun, c-myc and protein kinase C, from 60 Hz exposure and a linear reduction in ras p21 expression by a 72 Hz signal. 50/60 Hz signals altered c-jun and c-fos gene expression as observed by and Lagroye and Poncy (1998) and c-fos expression by Rao and Henderson (1996) and Campbell-Beachler et al. (1998). The ppSom gene is very important in human neurological disorders, and is regulated by calcium ions Capone, Choi and Vertifuille (1998).

Cell phone radiation (836.55 MHz) significantly altered c-jun transcript levels, Ivaschuk et al. (1997). Cell phone radiation significantly enhances the proto oncogene c-fos activity in C3H 10T 1/2 cells, from a 40 % ($p=0.04$) increase from a digital cell phone and a 2-fold increase ($p=0.001$) from an analogue cell phone, Goswami et al. (1999).

Hence proto oncogene activity is altered and enhanced in multiple independent experiments from ELF and RF/MW exposure, including cell phone radiation.

7.8.6 Immune system impairment by EMR

Impairment of the immune system is related to calcium ion efflux, Walieczech (1992) and to reduced melatonin, Reiter and Robinson (1995). Cossarizza et al. (1993) showed that ELF fields increased both the spontaneous and PHA and TPA- induced production of interleukin-1 and IL-6 in human peripheral blood. Rats exposed to microwaves showed a significant reduction in splenic activity of natural killer (NK) cells, Nakamura et al. (1997). Dmoch and Moszczynski (1998) found that microwave exposed workers had decreased NK cells and a lower value of the T-helper/T-suppressor ratio was found. Moszczynski et al. (1999) observed increased IgG and IgA and decreased lymphocytes and T8 cells in TV signal exposed workers. Quan et al. (1992) showed that microwave heating of human breast milk highly significantly suppressed the specific immune system factors for E.Coli bacteria compared with conventional heating. Chronic, 25 year, exposure to an extremely low intensity ($<0.1\mu\text{W}/\text{cm}^2$) 156-162 MHz, 24.4 Hz pulse frequency, radar signal in Latvia produced significant alterations in the immune system factors of exposed villagers, Bruvere et al. (1998).

Since calcium ion efflux and melatonin reduction are established biological effects of EMR exposure from ELF to RF/MW, impair immune systems should be observed in EMR exposures. Multiple independent evidence is available for RF exposures, down to extremely low chronic mean levels.

This evidence establishes that EMR is genotoxic. This occurs through enhancing free radical damage by reducing melatonin, by altering the signal transduction within cells in such a manner that proto oncogene activity is increased, and by reducing the competence of the immune system through both reducing melatonin and altering calcium ion homeostasis.

7.9 Conclusions:

These Bioelectromagnetic Principles scientifically sound. They are supported by a very large body of reliable internationally published peer-reviewed scientific research. They provide an integrative link between biology, EMR interactions, biological mechanisms and epidemiology. When considered with the supporting scientific evidence they provide a substantial challenge to the validity of the ICNIRP guideline.

8. The ICNIRP Guideline is seriously flawed and unlawful in New Zealand:

8.1 Environment Court Support:

The Environment Court (MacIntyre, 1996) declared that the New Zealand Standard (and hence the ICNIRP guideline) is “not decisive” in New Zealand law but that the Sections 5 and 3 of the RMA are the appropriate legal basis for public exposure to electromagnetic radiation (EMR). This requires evidence to be considered of actual and potential adverse effects. In considering the evidence before it, including evidence of actual or potential adverse effects which occurred about 2.4 and $2.9\mu\text{W}/\text{cm}^2$, the court set a public exposure condition for a cell site at that time and in that case of $2\mu\text{W}/\text{cm}^2$. This was 1% of the then

allowed public exposure in NZS 6609, and 0.4% of the recently adopted NZS 2772.1:1999, the ICNIRP guideline.

The sections of the law that this is based on are Section 5, which requires that we "Avoid, remedy or mitigate any adverse effect of an activity on the environment." The definition of the 'environment' in Section 2 includes 'people and communities'. The definition of effect, Section 3, includes 3(d) "any cumulative effect of itself or in combination with any other effect, regardless of scale, intensity, duration or frequency, including (3f) "any potential effect of low probability which has a high potential impact."

The fundamental basis of the New Zealand environmental law is the assessment of evidence of potential or actual effects of activities, available at the time of the decision. This rules out the use of a standard when there is evidence of effects are available at the time of the decision. The Chief Environment Court Judge, Judge David Sheppard, has accepted evidence and interpretation of the law that renders the ICNIRP guideline unlawful.

Additional strong reasons for rejecting the adoption of the ICNIRP guideline in New Zealand is the position that ICNIRP is based on 'established' effects whereas the legal evidence threshold in New Zealand is 'potential' effects, which have already been accepted by the Environment Court. It is grossly inappropriate for any country to adopt the ICNIRP guidelines for public health protection because it is scientifically challengeable as it is based on serious errors and omissions.

In an earlier case for which no epidemiological evidence was presented on adverse human health effects from power lines, *Transpower vs Rodney District Council*, Judge Sheppard defined the basis of a 'potential effect' as being "based on a plausible biological mechanism not mere innuendo".

The MacIntyre case was presented with evidence of plausible biological mechanism by Dr Richard Luben and epidemiological evidence of actual or potential human health effects by Dr John Goldsmith, with the exposure conditions of $2.9\mu\text{W}/\text{cm}^2$ and $2.4\mu\text{W}/\text{cm}^2$ associated with these effects being given by Dr Neil Cherry. Based on this evidence and the agreement of BellSouth that they could operate with a public exposure of $1.6\mu\text{W}/\text{cm}^2$, the public exposure condition of $2\mu\text{W}/\text{cm}^2$ was imposed. The court judgment also stated that this condition should be reviewed if there was any new evidence.

8.2 Environment Court Judgment error:

In the most recent case, the *Shirley Primary School vs Telecom*, a cell site case, it is submitted here that the Judge, Judge Jackson, made errors in law and evidence by ignoring the guidance given by Judge Sheppard, received evidence of potential or actual effects below $2\mu\text{W}/\text{cm}^2$. This included the North Sydney study, Hocking et al. (1997), presented by Dr Hocking, who recommended an exposure level of $0.2\mu\text{W}/\text{cm}^2$ based on his study. It also included the sleep disturbance study from Schwarzenburg, Switzerland, Altpeter et al. (1995) and the U.S. physical therapist miscarriage study of Ouellette-Hellstrom and Stewart (1993). The judge's findings accepted that there was a very low risk of childhood leukaemia, sleep disturbance and miscarriage, but allowed the ICNIRP guideline exposure level of $450\mu\text{W}/\text{cm}^2$ to be applied.

This is clearly challengeable as a misapplication of the provisions of the Resource Management Act, especially in the light of earlier, more senior guidance from Judge Sheppard.

9. The ICNIRP treatment of Biological mechanisms:

9.1 In appropriate reliance on a plausible biological mechanism:

One of the primary reasons many skeptics about EMR health effects, such as ICNIRP, use to dismiss studies that show statistically significant effects and even dose-response relationships, is their claim of the lack of a plausible biological mechanism. When a study reveals a significant biological effect at nonthermal levels the skeptics state that it must be independently replicated before it can be accepted as an established biological mechanism. Based on this criteria calcium ion efflux/influx, GABA fluxes, melatonin reduction, DNA damage, chromosome aberrations and altered proto oncogenes are established biological mechanisms. All have been reported from two or more independent laboratories, most in 4 or more laboratories.

9.2 ICNIRP RF/MW assessment of Calcium Ion Efflux:

ICNIRP cites only three calcium ion efflux papers of the over 30 which have been published. Two are cited as showing significant effects, Bawin et al. (1975) and Blackman et al. (1979). One is cited as showing no effect, Albert et al. (1987).

The overall conclusion, which applies to all biological mechanisms, including calcium ion efflux, states:

"Overall, the literature on athermal effects of AM electromagnetic fields is so complex, the validity of reported effects is so poorly established, and the relevance to human health is so uncertain, that it is impossible to use this body of information as a basis for setting limits on human exposure to these fields".

This is a carefully and deliberately constructed dismissal of athermal (nonthermal) effects so that epidemiological effects can also be dismissed for lack of a biological mechanism to justify dismissal. In challenge and contrast to this Dr Carl Blackman, Blackman (1990) concludes that calcium ion efflux is an established biological effect having considered about 20 papers.

9.3 ICNIRP ignores most evidence of genotoxicity:

The ICNIRP assessment cites and lead to genetic studies, and totally ignores the vast literature on DNA strand breakage, chromosome aberrations, oncogene activity enhancement, melatonin reduction and the Schumann Resonance interactions.

10. Reproductive outcomes: 100kHz-300GHz

10.1 The ICNIRP Statement:

There are several major errors and omissions in the ICNIRP (1998) assessment of reproductive effects, ICNIRP (1998), Figure 17.

Reproductive outcomes. Two extensive studies on women treated with microwave diathermy to relieve the pain of uterine contractions during labor found no evidence for adverse effects on the fetus (Daels 1973, 1976). However, seven studies on pregnancy outcomes among workers occupationally exposed to microwave radiation and on birth defects among their offspring produced both positive and negative results. In some of the larger epidemiological studies of female plastic welders and physiotherapists working with shortwave diathermy devices, there were no statistically significant effects on rates of abortion or fetal malformation (Källén et al. 1982). By contrast, other studies on similar populations of female workers found an increased risk of miscarriage and birth defects (Larsen et al. 1991; Ouellet-Hellstrom and Stewart 1993). A study of male radar workers found no association between microwave exposure and the risk of Down's syndrome in their offspring (Cohen et al. 1977).

Overall, the studies on reproductive outcomes and microwave exposure suffer from very poor assessment of exposure and, in many cases, small numbers of subjects. Despite the generally negative results of these studies, it will be difficult to draw firm conclusions on reproductive risk without further epidemiological data on highly exposed individuals and more precise exposure assessment.

Figure 17: The ICNIRP (1998) epidemiological assessment of reproductive effects, p504.

This includes misrepresentation of two studies, inadequate interpretation of three studies and omission of several relevant epidemiological studies and failure to cite the relevant animal studies. ICNIRP (1998) concludes that studies involving pregnancy outcome and microwave exposure suffer from poor assessment of exposure, small numbers of subjects and contrasting results. All of these claims and conclusions are wrong.

10.2 The studies of Daels (1973 and 1976):

The first claim is that there are two extensive studies on women treated with microwave diathermy to relieve the pain of uterine contractions during labour, with no evidence of adverse effects on the fetus, quoting Daels (1973 & 1976). Daels (1973 (4 pages) & 1976 (2 pages)). They are very small papers on an analgesic therapy for use in labour, and report on the subjective Apgar Score of the new-born child. The test is carried out about 60 seconds after birth. The score is the sum of indexes related to heart rate, respiratory effort, muscle tone, reflex irritability and colour. Ten is a perfect score. The test is carried out within 30 minutes of the exposure, 1 minute after birth. This is a small fraction of the cell cycle time and therefore cannot detect cellular damage.

These studies involve short-term microwave heating of the uterine area for 30 to 40 minutes during labour. They recorded a maximum neonate temperature of 37.8°C and amniotic fluid temperature of 36.5°C. These are well within the normal range. Heating was limited to levels where the mother felt skin heating as “agreeable”. Since most of the microwaves are absorbed in the surface skin layers the fetal exposure will be extremely small, see Hocking and Joyner (1995) below.

The Apgar Score showed that the “microwave group” had a slightly higher mean score of 9.1 compared to 8.8 for the “control group”. A Very low Apgar Score (0-3) indicates gross problems and have been correlated with long-term problems, such as significantly lower Bayley mental scores, Serunian and Broman (1975). Lan et al. (1991) found that low (4-6) and very low (0-3) Apgar Scores were significantly associated with low birth weight. In Daels the lowest Apgar Score was 7, within the normal range. The Daels papers show that the slight, imperceptible heating of the mother during delivery by microwave diathermy, results in a slight improvement in the Apgar Score, attributed to the more relaxed mother because of the warming.

A fully developed child is involved, exposed at extremely low levels for minutes immediately prior to birth, and assessed immediately after birth. There is no assessment of the developed pre-schooler to determine if there was any brain damage or developmental problems that could have resulted from a small risk of chromosome damage.

In Daels (1973) he simply states “*No undesirable side effects of microwave heating of tissues are known.*” He references a single study, Leary (1959) to note that overheating can be a rare complication. Thus Daels (1973 & 1976) are neither extensive studies nor about subsequent new-born health in the months or years following the birth and the exposure.

It is therefore totally inappropriate and grossly misleading to cite these as “extensive studies” of the impact of microwaves on the fetus. The exposure of the fetus is extremely low and very short. The studies are not extensive, they do not relate to developing fetus and there is no actual assessment of the long-term impact of the exposure on the children.

10.3 Interpretation of Physiotherapy Studies:

In assessing reproductive outcomes from physiotherapist studies it is important to distinguish short-wave exposure and microwave exposure, small study populations and larger study populations, and whole pregnancy including birth outcomes, in contrast to early pregnancy miscarriage alone. The effects of short-wave radiation are likely to be different from microwave effects. Small sample sizes may have elevated Risk Ratios but lack statistical significance solely by virtue of the small sample size.

10.4 Physiotherapist Studies Cited by ICNIRP (1998):

In ICNIRP 1998 three physiotherapist studies are cited, Kallen et al. (1982), Larsen et al. (1991) and Ouellet-Hellstrom and Stewart (1993).

Kallen and Larsen involve small samples and short-wave exposure, and whole pregnancy post-natal outcomes. Kallen et al. report significant increases in malformed children and perinatal deaths for physiotherapists using RF diathermy. Larsen et al. observed very few boys, and many more perinatal deaths, premature births and low birthweight children for therapists using shortwave diathermy. Given these confirming results the reviewers state however *“The results suggest further study is necessary before conclusions can be drawn.”*

A further study was carried out. Ouellet-Hellstrom and Stuart involves a very large sample, studies only early pregnancy (first trimester) miscarriage and finds only microwaves to have an effect. They observe a significant dose-response increase in first trimester miscarriage for female therapists using microwave diathermy. Following the Bradford Hill guidance, this is indicative of a cause and effect relationship. In addition to Larsen et al. and Kallen et al. this additional study confirms that RF/MW exposure of pregnant women is associated with adverse reproductive outcomes. Despite this ICNIRP found reasons why this data is difficult to interpret.

Several other studies were available prior to 1993 but they were not cited by UNEP/WHO/IRPA (1993). The total available published research on EMR associated reproductive effects was not cited by WHO (1993) nor by ICNIRP (1998).

10.5 Case by case assessment:

10.5.1 ICNIRP misrepresentation:

ICNIRP states that there were “no statistically significant effects on rates of abortion or fetal malformation” in Kallen et al. (1982). This is wrong. even though Kallen et al. involves small sample numbers they conclude “The only positive finding was a higher incidence of short-wave equipment use among the females with dead and deformed infant than among controls.” Very few therapists were involved with microwaves. Hence Kallen et al. associate fetal death and malformation with the use of short-wave diathermy equipment, with $p=0.03$. This is a statistically significant association, contrary to the ICNIRP claim.

10.5.2 Papers cited by ICNIRP:

Larsen et al. (1991), identified 54 cases with birth problems and 146 spontaneous abortion cases from Denmark. They found a significant increase in malformations, still birth, low birth weight, cot death and prematurely when working with short-wave diathermy.

Ouellet-Hellstrom and Stewart (1993) investigated early pregnancy miscarriage among Physiotherapists have been exposed to microwaves and shortwave radiation in the course of diathermy of patients. U.S. physical therapists used short-wave (27 MHz) and microwave (915 MHz and 2.45 GHz) diathermy. From a very large survey group 6,684 female Physiotherapists from the United States, reported using microwave or shortwave radiation at some time during their work history. A total of 1753 pregnancies involving first trimester miscarriage were matched to 1753 control pregnancies. This revealed a 7%, but non-significant rise in miscarriage associated with shortwave exposure and a highly significant 28%, OR= 1.28, 95%CI: 1.02-1.59, increase in first trimester miscarriage for

those exposed to microwaves, including a highly significant ($p < 0.005$) dose-response relationship, Figure 18a.

Figure 18a: Microwave exposure associated miscarriage for pregnant physiotherapists, Ouellet-Hellstrom and Stewart (1993).

Exposure levels were based on 3 minutes exposure per treatment to $600\mu\text{W}/\text{cm}^2$, a peak exposure level near the middle of the reported range. This gives $0.042\mu\text{W}/\text{cm}^2$ per treatment per month, to give a monthly mean dose-response based on treatments per month. The overall odds ratio was a $1a = 1.28$ ($1.02 - 1.59$). For all physiotherapists with no prior foetal loss the overall odds ratio was $OR = 1.26$ ($1.00 - 1.59$). There was a highly significant dose-response trend, $p < 0.01$.

In addition to the three studies cited in ICNIRP (1998) there are several others with are relevant.

10.5.3 Additional Studies not cited by ICNIRP (1998):

- Nordstrom, Birke and Gustavsson (1983) observed a significant decrease in "normal" pregnancies in high voltage substations in Sweden, almost exclusively as a result of congenital malformations when the father was a high voltage switchyard worker. Nordenson et al. (1988) measured a significant increase in chromosome aberrations in similar workers.
- A small group ($n=30$) of U.S. Military personnel exposed to radar had significantly lower ($p=0.009$) lower sperm counts, Weyandt et al. (1996).
- Vaughan et al. (1984), studying U.S. workers, found significantly increased risk of fetal death for last pregnancy for therapists, $RR=2.0$, $CI: 1.5-2.5$, $n=169$, and for electronic technicians, $RR= 1.5$, $CI:1.2-2.0$, $n=202$.
- Wertheimer and Leeper (1986) found a seasonal pattern of developmental delay and spontaneous abortion which significantly correlated with the use of times when electrically heated beds were used. They were not able to correlate the reproductive outcomes directly with electric field exposure. Subsequent studies have found this, confirming this result could well be EMR related.

- Taskinen et al. (1990) in Finland, with 204 cases, found increased spontaneous abortion with short-wave and microwave use: Note that the statistical significance is limited by the small sample sizes.

Electric therapies >5/week	OR= 2.0, CI: 1.0-3.9, n=17
Shortwaves >=5h/week,	OR= 1.6, CI: 0.9-2.7, n= 30
Microwaves,	OR= 1.8, CI: 0.8-4.1, n=13),

Stronger associations with ultrasound and heavy lifting:

Ultrasound >=20/week,	OR= 3.4, CI: 1.2-9.0, n=9
Heavy lifting, > 10 kg or patient transfers >=50 times/week,	OR=3.5, IC: 1.1-9.0, n=11

Odds ratios increased for pregnancies > 10 weeks:

Electric therapies	OR=2.2
Shortwaves	OR=2.5
Microwaves	OR=2.4
Ultrasound	OR=3.4
Heavy lifting	OR=6.7 .

Taskinen et al. conclude "Physical exertion during early pregnancy seems to be a risk factor for spontaneous abortion. The findings raise suspicion of potential harmful effect of shortwaves and ultrasound on the pregnancy, but no firm conclusion can be drawn on the bases of these results alone."

However, this study, in the context of all the other studies, is consistent and adds considerable weight to the conclusion that there are adverse health effects from RF/MW exposure. Taskinen et al. also found statistically significant increases in congenital malformations in the children of mothers using shortwave therapy. This confirms the results of Kallen et al, and Larsen et al.

Taskinen et al. (1990) was the only Scandinavian study to have a large enough sample to investigate the effects of miscarriage with microwaves. The sample was quite small (13), limiting the significance of the result. The Odds Ratio was (OR= 1.8, 95% CI 0.8-4.1). Exposure to ultrasound and short-wave showed significant increases in odds ratio for abortion after the 10th week of gestation, (OR = 3.4, $p < 0.01$ and OR = 2.5, $p < 0.03$, respectively). Taskinen et al. concluded: "The effect of shortwaves and ultrasound on the 'late' spontaneous abortions was significant and increased in a dose response manner."

- Sanjose et al. (1991) investigated the incidence of low birthweight and preterm delivery in Scotland, 1981-84, in relation to parent's occupation. They found statistically significant ($p < 0.05$) increases in low birth weight (RR = 1.4) and preterm delivery (RR = 1.8) for mothers who work in the electrical industry. People who work in "electrical industries" are recognized as being exposed to a wide range of EMR giving them more than average EMR exposures.

- Larsen (1991) found a non-significant elevation in congenital malformations in a small (n=54) group of RF exposed Danish physiotherapists, OR = 1.7, 95%CI: 0.6-4.3.
- In 1992 the American Journal of Epidemiology published a paper by Lindbohm et al. (1992) that observed a dose-response increase in miscarriage as a function of magnetic fields strength of exposure from VDTs, Figure 18b. Their data follows, including measured VDT ELF emissions:

Exposure			
Range	Mean	RR	95%CI
<0.13 μ T	0.09	1.0	Reference
0.13-0.3 μ T	0.21	1.9	0.9-3.9
>0.3 μ T	0.35	3.4	1.4-8.6

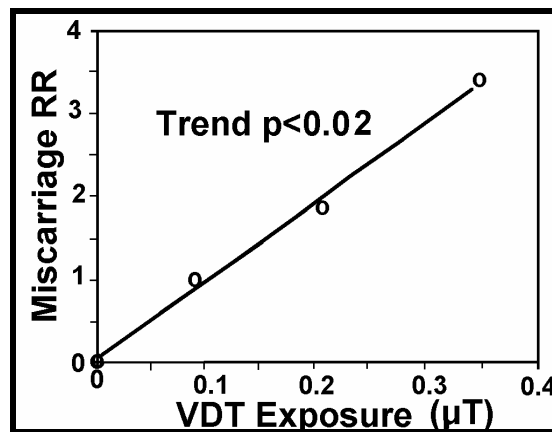

Figure 18b: ELF/RF/MW exposure from VDT usage increases miscarriage in a dose-response manner, Lindbohm et al. (1992).

- Evans et al. (1993) compared reproductive outcomes between Magnetic Resonance Workers and other groups. MRI workers had elevated outcomes compared with other workers but compared with homemakers they were highly elevated:

Outcome	RR	95%CI
Miscarriage	3.22	1.74-5.97 (p=0.0001)
Early Delivery	1.71	0.87-3.38
Low Birth Weight	1.52	0.52-4.41

- Juutilainen et al. (1993) observed a significant early pregnancy loss associated with "high" residential 50 Hz exposures ($\geq 0.63 \mu$ T at the front door), OR = 5.1 (1.0-25).
- Belanger et al. (1997) conducted a prospective study (N= 2967) to evaluate the relation between spontaneous abortion and the use of electrically heated beds. Electric blanket use was associated with increased spontaneous abortion, OR = 1.84, 95%CI: 1.08-3.13 for unadjusted data, and OR = 1.74, 95%CI: 0.96-3.15 for data adjusted for other risk factors such as alcohol, smoking, age and caffeine intake.

10.5.4 Summary and conclusions:

The ICNIRP reproductive assessment fails to take into account 11 relevant studies that reconfirm the conclusions of Kallen et al., Larsen et al. and Ouellet-Hellstrom and Stewart. This shows how limited and therefore unprofessional the ICNIRP assessment is.

The studies involving low frequency EMR exposure reinforce and support the RF/MW exposure studies through the EMR Spectrum Principle.

Vaughan et al. (1984), Taskinen et al. (1990), Sanjose et al. (1991), Lindbohm et al. (1992) and Larsen (1991) are consistent with Kallen et al. (1982) and Larsen et al. (1991) giving the conclusion that shortwave exposure takes longer to produce effects than do microwaves. Shortwave effects range from later pregnancy miscarriage, still birth, low birth weight, premature birth, cot death and congenital abnormalities.

Taskinen et al. (1990) and Ouellet-Hellstrom and Stewart (1993) confirm that microwave exposure is associated with early pregnancy miscarriage.

It is sobering to also note that breast cancer risk is over 4 times higher for women who miscarry in the first trimester, RR = 4.1, 95% CI: 1.5-11.3, Hadjimichael et al, (1986).

When all the studies are taken together they form a comprehensive and compelling body of research to show that microwave exposure of mothers leads to a significant increase in early pregnancy miscarriage, with two significant dose-response relationships, and that those using short-wave radio therapies and working in electrical industries, have more late pregnancy problems and malformed children. This amounts to a causal relationship between EMR exposure and adverse reproductive outcomes.

10.5.6 Plausible Mechanism:

The most likely mechanism is accumulated chromosome aberrations and damaged cells in the placenta and fetus because biophysics shows extremely small temperature increases can be expected from even very high RF/MW exposures.

Calcium ion efflux lead to the survival of damaged cells that carry their chromosome aberrations into future generations of cells. A reduction in melatonin reduces the elimination of free radicals which enhances the chromosome damage. Calcium ion efflux and melatonin reduction also impairs the immune system with allows a greater population of damaged cells to survive. Cells with damaged chromosomes are a known cause of spontaneous abortion.

According to Sandyk et al. (1992):

“The causes of spontaneous abortion can be divided into two main categories: those arising from chromosomal anomalies and those arising from abnormalities in the intrauterine environment. In the following communication, we propose that deficient pineal melatonin functions in early pregnancy may be causally related to the development of spontaneous abortions in cases where chromosomal anomalies or structural abnormalities of the uterus have been excluded.”

Microwaves are shown to be associated with DNA breakage in rats brains, Lai and Singh (1995, 1996, 1997), Sarkar et al. (1994) and Phillips et al. (1998), and to cause chromosome aberrations, Heller and Teixeira-Pinto (1959), Garaj-Vrhovac et al. (1990, 1991, 1992, 1993), Haider et al. (1994) and others. Lai and Singh (1997) show the links to melatonin reduction and free radicals.

ICNIRP (1998) quotes Cohen et al. (1977) which found no association between radar exposure and Down's syndrome in their off-spring. They failed to mention a previous paper from the same group, Sigler et al. (1965), which did find a significant risk from parental radar exposure.

Sigler et al. suggested that this result, along with research which found "tissue damage in humans and laboratory animals" and "a deleterious effect of rat testis" as evidence that microwaves might be ionizing radiation, since similar effects had been identified with exposure to ionizing radiation. We now know that chromosome aberrations do occur in microwave exposed subjects without the need for microwaves to be ionizing.

Flaherty (1994) presents "The effect of non ionizing electromagnetic radiation on RAAF personnel during World War II". He found in a group of 302 surviving veterans, men had a ratio of single to twin births of 41:1, women 38:1 and overall the ratio was 40:1. This contrasts with the ratio in the normal Australian population of 85:1. Hence radar exposed veterans had over twice the expected number of twins, a very significant result.

10.6 Animal Toxicology:

ICNIRP (1998) fails to refer to the significant research involving animal experiments on reproductive effects when exposed to RF/MW. Results range from testicular degeneration, resorption of the fetus and altered body weight at high but non-thermal levels of exposure to total infertility in multigenerational studies of mice exposed to $0.168\mu\text{W}/\text{cm}^2$ and $1.053\mu\text{W}/\text{cm}^2$, Magras and Xenos (1997). There are many animal studies showing that RF/MW is teratogenic, that is, it causes severe reproductive problems. Berman et al. (1982) introduce their paper by stating:

"It has been repeatedly shown that microwaves have teratogenic potential. Rats and mice have been used almost exclusively in these studies."

Berman et al. (1982) were extending the studies to hamsters. They investigated the teratogenic potential of microwaves on Syrian hamsters, using 2.45 GHz at power densities of $30\text{ mW}/\text{cm}^2$ for 100 minutes daily. This caused a temperature rise of $0.8\text{ }^\circ\text{C}$ and significant fetal resorptions or death ($p = 0.0012$), decreased fetal body weight ($p=0.0001$) and decreased skeletal maturity. Averaging this over a whole day the mean exposure is $2.08\text{ mW}/\text{cm}^2$. Maternal toxicity was not observed, only fetal damage and death. They conclude by comparing hamsters with mice.

"In mice, SAR's of 16 or 22 mW/g caused fetal changes. Comparing these two species, we see that 16 mW/g and above can cause decreased body weight and skeletal immaturity in mice, while only 9 mW/g in the hamster causes similar changes. Additionally, this lower SAR causes a significant increase in hamster fetal death (resorptions). Hamster fetus, appears to be

more susceptible to microwave radiation than the mouse, exhibiting fetotoxic changes at lower SAR values.”

Prausnitz and Suskind (1962) exposed male Swiss albino mice to 9.27 GHz microwaves, pulsed with a 2 μ s pulse at 500 Hz, 4.5 mins per day, 5 days per week for 59 weeks with an exposure level of 100 mW/cm². This is a thermal exposure load which would result in a temperature rise of about 2°C. This amounts to a mean weekly exposure of 22 μ W/cm².

Detailed autopsies were carried out on 60 irradiated and 40 control mice who died during the experiment. Two adverse effects were more severe in the exposed compared to the control animals.

- (1) Testicular degeneration (atrophy with no sperm) occurred in 29.8% (39/124) of the exposed animals and 7.1 % (4/56) of the control animals, RR = 4.2.
- (2) Cancer of the white cells or leukosis was seen in 26.5% (39/147) of the exposed animals compared to 13.0% (9/69) of the controls, RR= 2.04. This condition was described as monocytic or lymphatic organ tumours or myeloid leukaemia in the circulating blood.

In these mice significant and severe (4.2-fold) testicular damage and a 2-fold increase in the initiation of leukaemia occurred in association with a mean exposure of 0.22 μ W/cm².

Testicular damage has also been found in men who have radar exposures. Weyandt et al. (1996) studied U.S. service men who have radar exposures. **“The group of men with potential microwave exposures demonstrated lower sperm counts / mL (p = 0.009) and lower sperm/ejaculate (p= 0.027) than the comparison group.”**

Although as early as 1962 severe reproductive problems had been identified with and exposure regime averaging 0.22 μ W/cm² most of the research was carried out with the incorrect assumption that if an effect was real it would be demonstrated if the exposure was high enough. And if an effect was not detectable at extremely high levels of exposure, there was no way that an effect would occur at low levels of exposure.

Even so, high exposure experiments did show effects. Below shows the progression downwards until animal experiments have been carried out and found significant effects at the levels used in 1962 by Prausnitz and Suskind and are found in the vicinity of cell sites.

Chazan et al. (1983) investigated the development of murine embryos and fetuses after irradiation with 2450 MHz microwaves at 40 mW/cm². They found indications of retardation of development in the early period of gestation in mice exposed to thermal MW fields. During the second half of pregnancy an increase in the number of resorptions, stillbirths and internal hemorrhages was noted. The living fetuses had lowered body mass compared to the offsprings of sham-irradiated mice.

Berman, Carter and House (1982) also found reduced weight in mice offspring after in utero exposure to 2450-MHz (CW) microwaves using an exposure level of 28 mW/cm². They were exposed to for 100 minutes daily from the 6th through 17th day of gestation. This gives a mean exposure during that period of 1.9 mW/cm². These data demonstrate

that the decreased fetal weight seen in microwave-irradiated mice (-10 %) detected in utero and is retained at least 7 days after birth. Evidence from other published studies is presented to show that the retarded growth is persistent and might be interpreted as permanent stunting.

Suvorov et al. (1994) studied the biological action of physical factors in the critical periods of embryogenesis. The critical period in a chicken embryonic development (the 10-13 days of incubation) is revealed under total electromagnetic radiation. EMR is a physiologically active irritant which can influence functional state of the brain. The increased absorption of electromagnetic energy takes place in this incubation period. Its dynamics within 20 days of embryonic development has phasic, up and down character.

Electromagnetic exposure (4 hours a day) in the above mentioned period evokes a delay in embryo adaptive motor behavior (biofeedback learning). Morphological investigation shows significant pathological changes, specifically, destruction of share brain synapses. The delay in embryo hatching for a day is also detected. Radiation exposure within other periods of incubation (3-6th or 12-15th days) was not effective with respect to formation of normal motor pattern in biofeedback experiment. Unfortunately this paper is in Russian and no exposure levels are quoted in the English translation of the abstract.

The Australian ABC television investigative programme, Four Corners, claimed in a documentary on electromagnetic health effects, that in a factory which used radiofrequency heaters for sealing plastics, that of 17 women who worked at sealing machines, 14 had miscarried. Plastic sealers expose the operator to far higher levels that do physiotherapy diathermy devices. In association with the concern in Australia about the reproductive risks from plastic sealers, Brown-Woodman et al. (1989) exposed a set of rats to a repeated exposure to 27.12 MHz EM fields for 5 weeks. A reduction in fertility occurred as indicated by a reduced number of matings in exposed rats compared to sham-exposed rats, and a reduced number of conceptions after exposure. They conclude that:

"The data suggests that female operators could experience reduced fertility, if they remain close to the console for prolonged periods. This has particular significance for the physiotherapy profession."

Magras and Xenos (1997) responded to health concerns among residents living in the vicinity of an RF transmission tower in Greece, by placing groups of mice at various locations in relation to the tower. The mice fertility was monitored over several generations and related to the RF exposure. Figure 10 shows the fertility rate of the two exposed groups. Where group A the "Low" exposure group ($0.168 \mu\text{W}/\text{cm}^2$) became infertile after 5 generations and B the "High" exposure group $1.053 \mu\text{W}/\text{cm}^2$, became infertile after only 3 generations. This is a highly significant result because so few multi-generation studies have been done and the effects of this study occur at extremely low levels and the effect is total infertility.

The Greek study confirms the Australian study, but shows that over several generations the infertility is complete at very low levels of mean RF/MW exposure, Figure 18c.

Figure 18c: Multigenerational exposure of mice to low level RF leads to complete infertility.

10.7 Summary and conclusions about teratological animal studies:

There is repeated evidence of RF/MW induced infertility in rodents strongly showing that RF/MW have genetically damaged the cells of the animals. This suggests that there could be reproductive and genetic damage in RF/MW exposed humans. The epidemiological studies below confirm that there is, and at very low mean levels of exposure comparable to the exposure of the mice in Greece.

Developing sperm, embryos and fetuses are very vulnerable to damage from toxins. At critical times in utero development damage to certain organs occurs. With sufficient fetal or placenta damage a spontaneous abortion is initiated. At other exposure levels and timing of damage a still birth can result. Thermal levels of microwave exposure has produced retardation of development if exposure is in early pregnancy, and resorptions, still births and hemorrhages with exposure in the second half of the pregnancy.

A much lower microwave dose was associated with significant reduction in birth weight and permanent stunting and slowing of bone hardening. Changes in chick embryo biofeedback learning is observed and testicular atrophy was observed with a mean exposure to a radar-like signal averaging $22 \mu\text{W}/\text{cm}^2$ over a week. Total infertility occurred in mice after 5 weeks of exposure to $0.17 \mu\text{W}/\text{cm}^2$.

Thus in 1962 and 1997 it is been shown that chronic mean low level microwave exposure of animals leads to very significant adverse reproductive effects in males and females down. The effects were still significant at exposures of 0.22 and $0.17 \mu\text{W}/\text{cm}^2$. These are close to the level of the lowest published results for calcium ion efflux, 0.00015 W/kg ($0.08 \mu\text{W}/\text{cm}^2$) Schwartz et al. (1990).

RF/MW radiation causes significant birth and reproductive damage in exposed animals down to very low short-term and extremely low average exposure levels.

10.8 Reproductive Health Effects Conclusions:

The ICNIRP (1998) assessment of reproductive effects from RF/MW exposure is severely flawed. Animal studies show that chromosome aberrations and single and double strand DNA breakage occurs with EMR exposure, mice and rats have pregnancy, birth and fertility problems associated with EMR exposure which are also found in exposed human populations. There is consistency within human studies and between human studies and animal studies. Many human studies show statistically significant adverse reproductive outcomes. Two human studies, Lindbohm et al. (1992) and Ouellet-Hellstrom and Stewart (1993), gave a statistically significant dose response relationship. This study allows an exposure assessment to be carried out, along with the multigeneration mice study, Magras and Xenos (1997).

This evidence supports a causal relationship between EMR exposure and serious adverse reproductive outcomes such as miscarriage, premature, still birth, low birth weight, SIDS and congenital malformations.

10.9 Exposure Assessment:

Ouellet-Hellstrom and Stewart (1993) report that the microwave exposure was primarily from leakage, which at waist level was measured in the range 80 - 1200 $\mu\text{W}/\text{cm}^2$. At 15 cm from the source the highest reading was 15 mW/cm^2 . The therapist needs to be leaning over the patient during the therapy to receive this dose. This is highly unlikely when the machine is turned on. Even so, this is not sufficient to cause a surface heating of the skin in the few minutes it is likely to involve. Hocking and Joyner (1995) show that microwaves produce very small SARs with the uterus, in the following Figure 19.

Figure 19: Specific absorption rate (SAR) profile across the uterus for a small woman exposed to 1 mW/cm^2 , from Hocking and Joyner (1995).

In their table 2 Hocking and Joyner (1995) show maximum SARs in the uterus for the conditions in Figure 11 for short-wave (27.12 MHz) of 0.209 W/kg, for microwave (915 MHz) of 0.023 W/kg and for microwave (2.45 GHz) of 0.000027 W/kg.

Gandhi (1990) gives the relationship between SAR and temperature increase. The heating rate given is $0.0045 \times \text{SAR } ^\circ\text{C}/\text{min}$. With a maximum exposure time per treatment of 5 minutes, and an external field intensity of 1,200 $\mu\text{W}/\text{cm}^2$, the heating of the fetus will be 0.0055, 0.00062 and 0.00000073 $^\circ\text{C}$, respectively. Not even at 15 mW/cm^2 does the

short-wave exposure can produce a detectable heating effect in the uterus environment (0.071°C).

Since an acute thermal mechanism can be ruled out it is appropriate to calculate and use the cumulative average dose to determine the range of the exposure regime.

It is not the habit of therapists to stand close to the patient during the diathermy. In many cases the therapist leaves the room while the 15 to 30 minute diathermy is carried out. Hence a conservatively long exposure period of 2 minutes is chosen to be associated with the exposure range of $80 - 1200 \mu\text{W}/\text{cm}^2$. The dose-response relationship is expressed in terms of treatments per month.

One treatment per month is associated with a mean monthly exposure in the range 0.0038 to $0.056 \mu\text{W}/\text{cm}^2$, and a mean exposure of $0.03 \mu\text{W}/\text{cm}^2$.

Table 3: Estimated mean exposure ranges, from Ouellet-Hellstrom and Stewart (1993).

	No. of Exposures per Month		Odds Ratio	Exposure Regime ($\mu\text{W}/\text{cm}^2$)	
				Mean	Range
All pregnancies	0		1.00	0.0	-
	<5	(2.5)	1.05	0.08	0.0095-0.14
	5-20	(12.5)	1.50	0.38	0.048 - 0.7
	>20	(25)	1.59	0.75	0.095 - 1.45

This table shows the results from Ouellet-Hellstrom and Stewart (1993) for microwave exposure for all pregnancies. The Number of exposures in brackets is the assumed mean number of treatments in the calculation of the Exposure regime.

There is a 5 % increase in miscarriage associated with a mean microwave exposure of $0.08 \mu\text{W}/\text{cm}^2$. One treatment per month is associated with a monthly mean exposure of $0.03 \mu\text{W}/\text{cm}^2$, so that this is the Level of Lowest Observed Effect. This is totally consistent with the calcium ion efflux and animal toxicology experiments.

Hence for reproductive effects the Level of Lowest Observed Adverse Effect is $0.03 \mu\text{W}/\text{cm}^2$.

11. Cancer Assessment:

11.1 Laboratory Experiments:

I have only alluded to some of the cell and animal laboratory studies to demonstrate the consistency of the flawed scientific approach taken by ICNIRP.

The effect of microwaves neoplastically transforming a standard mice embryo cell line, a cell line which has been used several times in chemical carcinogen assessment are treated in the same inaccurately dismissive manner, p507, referring to the work of Balcer-Kubiczek and Harrison (1991). These researchers carried out a series of very careful and

extensive laboratory assessments using a standard mouse cell line. One of their most significant results is presented below, Figure 19.

Figure 19: Dose response relationship for the induction of neoplastic transformation of C3H/10T1/2 cells by a 24 h exposure to 2.45 GHz microwaves at specific absorption rate indicated on the abscissa with or without TPA post-treatment for 8 weeks (Balcer-Kubiczek and Harrison (1991).

This is a clear and simple result. TPA is a known and widely used cancer promotor. Together with TPA, microwaves significantly increase the number of neoplastically transformed cells in a significant dose response manner. Dr Balcer-Kubiczek states in a book chapter in 1995, Balcer-Kubiczek (1995):

“In 1985 we published the first evidence indicative of EMF carcinogenesis at the cellular level.”

Further on Dr Balcer-Kubiczek states:

“The mouse data of Szmigielski et al. (1982) are also consistent with a general picture emerging from our in vitro data, in that 2.45 GHz microwaves, and possibly 60 Hz magnetic fields, seem to act as an initiator or carcinogen, rather than as a promoter of malignant transformation.”

This is a very different and much stronger view than expressed by the ICNIRP review when it describes this work by saying: “This finding suggests that pulsed microwaves may exert co-carcinogenic effects in combination with a chemical agent that increases the rate of cell proliferation of transformed cells. To date, there have been no attempts to replicate this finding, and its implications are unclear.”

The use of the word “may” when the effect clearly does occur is wrong. The implication is clear if you want to see it, which the reviewer obviously does not. In context, animal skin, when treated with TPA or similar chemical cancer promoters, has the rate of cancer cell formation increased by microwaves. This experiment shows that it also does happen at the cellular level. That is, microwaves are carcinogenic at the tissue and cellular level. It is then not surprising that epidemiological studies also show that RF/MW increase cancer. But this review ignores and misrepresents that evidence too.

The extensive research into Melatonin and its implications are totally ignored.

12. Epidemiology of Cancer:

12.1 Summary of ICNIRP's assessment:

ICNIRP (1998) p 504 concludes by referencing one review (UNEP/WHO/IRPA 1993), and 13 papers covering 11 studies. The UNEP/WHO/IRPA 1993 is limited by citing only 6 epidemiological studies and, through not reviewing the actual results, contains errors, which are propagated through to the ICNIRP assessment.

In ICNIRP 1998, only 13 papers are cited directly:

1. **Barron and Baraff (1958):** The study group is too small (226) and the follow up period (4-13 years from first exposure) is too short to detect cancer. Cancer is not one of the paper's studies chosen outcomes. It is grossly dishonest and misleading to include this paper in a cancer assessment and to cite it as showing that there are no cancer risks from exposure to radar.
2. **Robinette et al. (1980):** Is widely claimed to show no effects when its data does show significant adverse human health effects, including a significant dose response relationship.
3. **Lilienfeld et al. (1978):** Is widely claimed to show no effects when its data does show significant adverse human health effects, including neurological, cardiac and cancer effects and includes a significant dose response relationship for rates of sickness as a function of years in Moscow.
4. **Selvin et al. (1992):** Is widely claimed to show no effects when it was aiming to develop an epidemiological method relating to spatial clustering. Its data does show significant adverse human health effects, including significant dose response relationships when radial cancer rates are related to radial exposure measurements.
5. **Beall et al. (1996):** Is quoted by ICNIRP as failing to show significant increases in nervous system tumours, when it does, and includes a significant dose response relationship between years of exposure and rates of brain tumor for computer programmers.
6. **Grayson (1996)** Is quoted by ICNIRP as failing to show significant increases in nervous system tumours, when it does show a significant increase in brain tumor for RF/MW exposed personnel.
7. **Rothman et al. (1996a):** ICNIRP acknowledges that it is still too early to observe an effect of cancer incidence and mortality from mobile telephone use as yet.
8. **Rothman et al (1997b)** ICNIRP acknowledges that it is still too early to observe an effect of cancer incidence and mortality from mobile telephone use as yet.
9. **Szmigielski et al. (1988):** finds significant increases in cancer across the body, but especially leukaemia incidence and mortality among Polish Military personnel

exposed to radio and radar. ICNIRP says is difficult to interpret because neither the size of the population nor the exposure levels are clearly stated. In fact the Polish Military microwave exposure regime is presented and the group is described by the authors as "large and well controlled".

10. **Szmigielski (1996)**: ICNIRP acknowledges that Szmigielski found significant increases in leukaemia but criticizes the exposure assessment and the description of the population. Again, the overall group exposure regime is well described, but as in all large population studies, individual exposures are not monitored but group exposures can be well classified.

- 11-13. **Hocking et al. (1996)**, (12.) **Dolk et al. (1997a)** and (13.) **Dolk et al. (1997b)** are acknowledged as "suggesting a local increase in leukaemia incidence" in populations living in the vicinity of TV/FM transmission towers, but ICNIRP calls the results "Inconclusive".

The overall cancer assessment conclusion that: "Overall, the results of the small number of epidemiological studies published provide only limited information on cancer risk."

This conclusion is mistakenly based on flawed previous but closely linked assessments, UNEP/WHO/IRPA (1993), failure to review the data on effects (2, 3, and 4), incorrect claims of no significant effects when such effects are reported (5 and 6), inappropriate dismissal of significant studies (9 and 10) and inappropriate devaluing of residential studies (11, 12 and 13). A systematic and independent analysis of the data in these papers reveals a consistent and significant increase in cancer in this set of studies. Also, many other studies exist which add considerable weight to this conclusion.

12.2 Much more evidence of RF/MW induced cancer is available:

Zaret (1977), Lester and Moore (1982 a,b) and Lester (1985), Milham (1985, 1988), Thomas et al. (1987), De Guire et al. (1987), Archimbaud et al. (1989), Hayes et al. (1990), Tornqvist et al. (1991), Maskarinec and Cooper (1993), Band et al. (1996), etc. In addition, the reviews of Goldsmith (1995, 1996, 1997a,b) are ignored. Several other papers are relevant. Occupational cancer studies identify a wide range of exposure agents, including RF/MW in occupational groups. For example, for "electrical, electronic manufacture and communications", such as Kaplan et al. (1997), who found an elevated risk of brain tumour (OR=2.2 (0.5-9.3)). Cantor et al. (1995) found significant increases in breast cancer for RF/MW exposed women in the United States. Thus there is at least twice as many papers available than those cited by ICNIRP.

It is a difficult and challenging task for an individual scientist to take on and criticize the largest and most prestigious bodies in the world, such as the WHO and ICNIRP. However, science not only allows this to occur, but supports and even demands a comprehensive review of the data contained in the published material, an inter-comparison between studies and an accurate quotation of the results and analyses given. It also supports correction of analyses where errors are identified, and new analyses where data suggests that more can be shown by standard scientific methods.

The summary above gives a strong indication of the ways in which ICNIRP have selectively used and consistently misquote the studies they have chosen to assess. Hence the conclusions which should be drawn are quite different than those ICNIRP

arrived at. In order to substantiate the brief claims made above this review will outline and list the detailed data contained in the studies cited.

12.4 Data analysis and presentation principles:

First I will set out some principles and then present the detailed data.

- A significant problem of principle is involved here. It is easy to make a simple claim to dismiss as study of effects while it takes a substantial presentation to correct such a misleading claim.

Simple incorrect arguments are consistently used and internally reinforced in review after review. Claims are simply made and to correct them requires detailed and comprehensive scientific analysis and review.

- It is easier to present biased conclusions than to falsify data.
- Every scientist is a person with a degree of subjectivity and bias. Hence science uses principles and methods involving careful checking and peer review. Basic scientific training makes it very difficult (though not impossible) for a scientist to falsify data.
- Analysis of data is more subject to error and bias in its use and interpretation. Errors can be simple arithmetic errors or errors in programming and data entry. Checking procedures are usually in place to significantly reduce the chance of this occurring.
- Subjective bias is frequently involved in the choice and interpretation of statistics which makes the principles of the application of statistical methods and agreed systems of interpretation vital.
- Epidemiology is the basic science of preventive medicine and public health, and biostatistics is the quantitative foundation of epidemiology, Jekel et al. (1996).
- The test of statistical significance:

In epidemiology it is agreed that a statistically significant result is one which reaches the 1-in-20 or 5 % threshold for statistical probability. In calculating the value of the statistical probability or p-value (p), a single direction effect is tested against a one-tail distribution while a bi-directional effect is tested against a two-tailed distribution. This requires half the population to achieve statistical significance when searching for an adverse effect than when the hypothesis involves the possibility of a positive and a negative effect.

- Epidemiology deals with chronic exposure of populations whereas the ICNIRP guideline is based on acute thermal effects on individuals. An important characteristic of epidemiology is its ecologic perspective. People are seen not only as individual organisms but also as members of communities in a social context.

- Classical epidemiologist studies the community origins of health problems. Classical epidemiologists are interested in discovering risk factors that might be altered in a population to prevent or delay disease or death.
- Death is only one of the outcomes of concern. In general many more people are made ill by a disease agent than those who die of it. Illness has a significant personal, social and economic cost which makes the prevention of illness a worthy goal.
- Dose response relationships are indicative of causal relationships and need to be taken very seriously, Bradford Hill (1965).
- Chronic mean exposures are much lower than acute peak exposures. Health risks such as cancer are related to cumulative cellular damage from inaccuracy on DNA repair processes and failure of the body to eliminate genetically damaged cells. Hence the chronic mean exposure is the appropriate metric for assessing health effects.
- There are a large number of studies that involve RF/MW exposures and show elevated and significantly elevated cancer incidence and mortality. These are dismissed by WHO and ICNIRP assessors because of the lack of a well defined exposure measurement. Dr Szmigielski confirms, pers.comm., that even the highest acute military exposures in the Polish Military study are nonthermal, and are associated with daily average exposures around 1-5% of the daily peak exposure, and lifetime mean exposures about 20-30% of the daily mean work day exposure. These chronic mean exposures are at a small fraction of the ICNIRP guideline.
- Significant increases in cancer are also found in residential RF/MW exposures around TV/FM towers with annual mean exposures around 15% of the direct exposure at the primary residence. Hence there is a large body of epidemiological evidence showing significant increases in cancer in RF/MW exposed populations whose chronic mean direct exposures of less than 0.1 to $0.2\mu\text{W}/\text{cm}^2$, and hence involve chronic mean exposures in the range 0.015 to $0.03\mu\text{W}/\text{cm}^2$. This firm knowledge of the actual mean exposure is not necessary in order to revise the exposure standard when significant health effects occur at exposure levels of less more than 1000 times below the present standard.

13. Detailed evaluation of ICNIRP cited papers and reports:

13.1 Barron and Baraff (1958): "Medical considerations of exposure to microwaves (radar)"

The initial study contained 226 radar exposed workers, and 88 in the control group. In the radar group 37 had 5 - 13 years of exposure and 83 has 2 - 5 years. In the extended study 109 new workers were added placing them generally in the 2-5 year group. This is far too short a time for most cancers to appear, with latencies typically between 8 and 30 years. An article in the same volume of the J.A.M.A. records the initiation of a study on thousands of U.K. Radiologists, some of whom had started work in 1920. It is stated that in 1958 it is too early to see an increase in X-ray induced cancer and the sample is too small.

With the working age incidence of all cancers at about 100 per 100,000 per year, over the 4 years of this study the probable number of normally occurring cancers would be 0.9. This paper cannot and does not assess cancer risk from radar exposure.

This paper does report a high incidence of headache and nervousness, so called subjective or neurasthenic symptoms. This is consistent with stronger later findings, e.g. Djordevic et al. (1979), Lilienfeld et al. (1978), Hocking (1998), Mild et al. (1998) and Frey (1998). The study also reports significantly higher red blood cell counts and lower monocytes, and elevated white blood cell counts and reduced eosinophils and polymorphonuclear cells in the radar-exposed group compared with the control group. Altered blood cell counts were also found in radar exposed groups in the U.S. Embassy in Moscow, Tonascia and Tonascia (1976) and in radar technicians, Goldini (1990).

Barron and Barraff did not assay for chromosome aberrations and DNA breakage. Laboratory techniques were not as advanced in 1958 and they are now.

To include this study in a cancer risk assessment is knowingly misleading and deceptive. This level of bias and error is unbecoming of an international assessment of quality and merit. This, along with several other similar examples, must bring the scientific objectivity and professional credibility of the person or group who produce this assessment into serious question.

13.2 Robinette et al. (1980): "Effects upon health of occupational exposure to microwave radiation (radar)"

13.2.1 Introduction

This is one of two epidemiological studies which ICNIRP states "found no evidence of increased morbidity or mortality from any cause". Both WHO (1993) and ICNIRP (1998) treat this as a large and reliable study which shows that there are no effects from radar exposures.

Epidemiological studies regarding cancer are affected by the complexities and long time scales involved in the initiation, promotion and progression of cancer. This process can take decades from the initial cell damage and genetic transformation of cells to the development of tumors and malignant cancers. To some extent the individual complexities and the complex nature of post war exposures to carcinogens over 20 years are smoothed by considering large populations. This study involves around 40,900 sailors with advanced technical training who served on ships during the Korean War and were exposed to radio and radar signals. Their mortality statistics and health status about 20 years later was obtained and analyzed for evidence of differences which could be related to the RF/MW exposure. If the EMR exposure had caused a great amount of initiation and/or promotion of cancer then this study has the ability to reveal it.

An early challenge was to identify exposure groups so that the health status of a large group with lower mean exposures could be compared with a group that had received higher mean exposures. Comparing technical sailors with similar age structures reduced confounding. The naval advisors recommended that operators of radio and radar would

have lower mean exposures compared with those sailors who repaired and maintained the radio and radar equipment. Hence the low exposure group included Radioman (RM) and Radarman (RD). The technical people, including Electronics Technician (ET), Fire Control Technician (FT) and Aviation Electronics Technician (AT) were placed in the high exposure group.

A fourth technical group, Aviation Electrician's Mate (AE), a group which is clearly involved with repairs and maintenance, was placed in the operators group, the low exposure group. The AE group has a moderately high mortality rate and plays the role of diluting the difference between the groups.

The problem of high exposures for the radar and radio operators on ships was pointed out when the preliminary results were presented to a conference, Robinette and Silverman (1977).

13.2.2 Hazard Number Assessment:

Amongst those who were originally allocated to the exposed group, i.e. ET, FT and AT, around 5 % (1233 men) were randomly chosen to be assessed for individual exposure through a job matrix estimate of their Hazard Number. The results of this are in the following table:

Table 4: Distribution of assessed Hazard Number for the three assumed high exposure groups, Robinette et al. (1980).

Hazard Number	Electronics Technician (ET) %	Fire Control Technician (FT) %	Aviation Electronics Technician (AT) %
0	27.8	6.6	12.5
1 - 2000	28.3	23.4	16.9
2000-5000	20.0	31.1	17.6
5001+	10.6	25.8	48.6
Unknown	13.3	13.1	4.3
Mean HN	1610	2871	3701

There is a clear overlap between these groups with all groups having a large number in the 2000 + Hazard Number. There is a clear gradient in the proportion of each group with 5000+ Hazard Number.

13.2.3 Health survey results:

From the exposure survey there was a group of individual for whom each person was assigned a Hazard Number that was proportional to his exposure risk. Of those who had died, they identified 63 sailors with Hazard Number of 0, 160 with 1-5000 and 86 with 5001+. The mortality results are presented in Table 5.

Table 5: Number of deaths from disease and mortality ratios by Hazard Number: US enlisted Naval personnel exposed to microwave radiation during the

Korean War period, from Table 9, Robinette et al. (1980). The Rate Ratio is calculated as the ratio of the Mortality ratio for Hazard Number 5001+ exposure and 0 Hazard Number exposure.

Cause of Death	No.	Hazard Number			Trend		
		0	1-5000	5001+	p-value	RR	95%CI
All diseases	309	0.82	0.91	1.23	0.03	1.50	1.08-2.08
Malignant Neoplasms	96	0.99	0.90	1.44	N.S.	1.45	0.83-2.52
Digestive Organs	20	1.49	1.14	0.78	N.S.	0.52	0.13-2.08
Respiratory Tract	24	0.82	0.86	2.20	<0.05	2.68	0.84-8.55
Lymphatic and hematopoietic System	26	1.09	1.04	1.64	N.S.	1.50	0.52-4.32
Other Malignant neoplasms	26	0.78	0.70	1.17	N.S.	1.50	0.52-4.32
Disease of Circulatory System	150	0.94	0.83	1.17	N.S.	1.24	0.79-1.94
Other Disease	63	0.30	1.13	1.08	N.S.	3.60	1.14-9.20

Given the exposure dilution factors, all but digestive organs would probably have $RR > 2$ and be significantly be increased. This small sample analysis shows a significant dose response trend for mortality from all diseases ($p=0.03$) and for Respiratory Cancer ($p<0.05$). This is remarkable given the exposure dilution. The analysis also shows that for every disease cause but one there is an elevated risk of mortality due to a range of cancers, Circulatory Disease and Other Disease.

The mean Hazard Number for each group is calculated using a mean hazard number of 0, 1000, 3500 and 6000 for the defined ranges. The mean exposure estimate also shows a gradient and suggests that the best dichotomy will be achieved by comparing AT as a high exposure group to ET as a low exposure group. This was not done by Robinette et al. who preferred to compare ET with the FT and AT groups combined (FT+AT). This maintains larger numbers in the high exposure group by reduces the exposure separation.

The mortality dose-response gradient persists when the total mortality rate is calculated for the ET, FT and AT groups: $MR(ET) = 1.0$; $MR(FT) = 1.29$; and $MR(AT) = 1.79$.

Having identified that the FT and AT groups had higher hazard numbers than the ET group, Robinette et al. combined FT + AT and compared their mortality rates with ET, Table 6. Table 6 shows elevated mortality rates compared with the ET group, for all causes of death listed. The text records that they are significantly elevated for All Disease ($p<0.01$) and Other Diseases ($p<0.01$).

Their Table 5 sets out the mortality data by cause of death for each occupational group, giving the opportunity to compare AT rates with ET rates of mortality. The results are shown in Table 6. In Table 5 where exposures are more dichotomized, mortality due to Malignant Neoplasms and Lymphatic/Hematopoietic cancers are both significantly elevated but when FT and AT are combined these results are no longer significantly different. It is interesting too that in the dose-response analysis using the individual's hazard number, respiratory cancer shows a significant trend, but in these occupational group comparisons this cancer is elevated but not significantly elevated. The

comparisons between Tables 6 and 7 clearly show the effect of dilution through combining the FT and AT groups.

Table 6: Mortality rates, Risk Ratios and Confidence Intervals between the ET group and AT group of US enlisted personnel exposed to microwave radiation during the Korean War.

Cause of death	No.(FT+AT)	ET	FT+AT	RR	95%CI
All diseases	140	0.83	1.19	1.43	1.14-1.79
Malignant Neoplasms	40	0.95	1.18	1.24	0.83-1.86
Digestive Organs	8	1.10	1.19	1.08	0.44-2.65
Respiratory Tract	9	1.13	1.15	1.02	0.45-2.33
Lymphatic and Hematopoietic System	11	1.06	1.40	1.32	0.61-2.87
Other malignant neoplasms	12	0.68	1.06	1.56	0.72-3.37
Diseases of the Circulatory System	64	0.85	1.08	1.27	0.92-1.75
Other disease	36	0.61	1.46	2.39	1.45-3.94

Table 7: Mortality Incidence per 1000 and Risk Ratio (AT/ET) as an indication of the high exposure (AT) to low exposure (ET) difference.

Causes of Death	Exposure		Risk Ratio	95 % CI
	Low	High		
All Deaths	33.7	60.5	1.79	1.52 - 2.12
Accidental Death	13.5	29.6	2.20	1.72 - 2.82
Motor Vehicle Death	6.3	6.1	0.97	0.60 - 1.59
Suicide, Homicide, Trauma	4.4	6.1	1.38	0.83 - 2.29
Suicide	3.4	2.7	0.80	0.39 - 1.63
All Diseases	15.2	23.5	1.55	1.19 - 2.01
Malignant Neoplasms	5.0	8.2	1.66	1.06 - 2.60
Digestive and Peritoneum	1.1	1.2	1.07	0.35 - 3.21
Respiratory	1.2	2.1	1.75	0.72 - 4.25
Eye, Brain, CNS (FT/ET)	0.4	0.9	2.40	0.57 - 10.03
Skin	0.2	0.6	2.66	0.45 - 15.94
Lymphatic and Hematopoietic	1.4	3.1	2.22	1.02 - 4.81
Circulatory System Disease	7.6	9.5	1.24	0.83 - 1.85
Digestive System Disease	0.8	2.7	3.27	1.35 - 7.89
Other Diseases	1.6	2.7	1.71	0.78 - 3.74

This shows elevated Risk Ratios for all causes of death except motor vehicle and suicide. Significant increases in mortality were found for All Diseases, Malignant Neoplasms, and Lymphatic and Hematopoietic cancer. Very significant increases were found for All Causes of death, Accidental Death and Death from diseases of the Digestive System.

Because of the uncertainty is true position of the AE group, who were repairers that were placed in the operators group, Dr John Goldsmith prepared the following diagram which links the mortality rates of low, medium and high exposures as reflected by the job exposure matrix survey, Figure 20.

Figure 20: Naval occupations grouped by exposure category, showing dose response increases in mortality for all mortality, all disease, cancer and Lymphatic/Leukaemia. Low exposure (RM+RD), Intermediate exposure ET+FT), High exposure (AT).

Grouping occupational groups according to exposure levels also reveals dose-response increases for Total Death, All Disease, All Cancer and Lymphatic/hematopoietic Cancer, Figure 20.

Morbidity Data:

Robinette et al. obtained two morbidity data sets. The first was from the periods 1952-54 and 1956-59 for admissions to naval hospitals. This is very close to the period of exposure and allows little time for cancers to develop. The second data set was from Veterans' Administration Hospitals for the period 1963-76.

For the immediate post-war data set the following significant increases in sickness were identified by Robinette et al.:

- Diseases of the ears, nose and throat ($p < 0.01$),
- Acute respiratory disease ($p < 0.01$),
- Other respiratory disease ($p < 0.02$),
- Diseases of the urinary and male genital organs ($p < 0.05$), and
- Accidents, poisonings and violence ($p < 0.001$).

Table 8: Number of hospitalizations and hospitalization rates per 10,000 per year, in VA hospitals, 1963 -1976, by diagnosis and exposure class: US enlisted Naval personnel exposed to microwave radiation during the Korean War period. The significance p-value is calculate from the Mantel-Haenszel Chi-squared estimate.

VA diagnostic class	Total		ET		High exposures		FT + AT			p-value
	No.	Rate	No.	Rate	No.	Rate	RR	95% CI		
Infective, parasitic	42	1.5	24	1.3	18	1.9	1.46	0.79-2.69	0.26	
Neoplasms, malignant	34	1.2	17	1.0	17	1.8	1.80	0.92-3.53	0.04	
Neoplasms, other	26	0.9	9	0.5	17	1.8	3.60	1.60-8.08	<0.001	
Allergic, endocrine system, metabolic and nutritional dis.	77	2.8	41	2.3	36	3.8	1.65	1.05-2.58	0.01	
Blood, blood-forming organs	17	0.6	5	0.3	12	1.3	4.33	1.53-12.3	0.001	
Alcoholism	105	3.8	45	2.5	60	6.3	2.52	1.71-3.71	<0.001	
Other mental disorders	276	10.1	166	9.3	110	11.6	1.25	0.98-1.58	0.02	
Nervous system, sense org.	106	3.9	58	3.2	48	5.1	1.59	1.08-2.33	0.009	
Circulatory	123	4.5	68	3.8	55	5.8	1.53	1.07-2.18	0.007	
Respiratory	80	2.9	43	2.4	37	3.9	1.63	1.05-2.53	0.014	
Digestive	255	9.3	132	7.4	123	13.0	1.76	1.38-2.25	<0.001	
Genitourinary	82	3.0	45	2.5	37	3.9	1.56	1.01-2.41	0.02	
Skin, cellular	61	2.2	33	1.8	28	2.9	1.61	0.97-2.66	0.04	
Bones, organs of movement	80	2.9	36	2.0	44	4.6	2.30	1.48-3.57	<0.001	
Trauma	108	3.9	53	3.0	55	5.8	1.93	1.32-2.81	<0.001	
Symptoms, ill-defined cond., special exams and other	151	5.5	85	4.8	66	6.9	1.44	1.04-1.99	0.007	
Person-years (1000)	27.39		17.89		9.50					

Table 8 gives a more detailed description of the results of the later morbidity data set. It is not inconsistent with the significant results cited by Robinette et al. but it does show a wider range of significant adverse health effects.

In the later VA compensation data Robinette et al. found significantly increase in sickness for Musculoskeletal system and other organs, including:

- Loss of part extremities, osteomyelitis and neoplasms of bone or muscle ($p < 0.001$);
- Organs of special sense which includes eye cataracts ($p < 0.05$);
- Respiratory system, excluding pulmonary tuberculosis ($p < 0.01$);
- Cardiovascular system ($p < 0.001$); and
- Mental disorders, including psychoses, psychoneurotic disorders and so-called "psychophysiological disorders" ($p < 0.05$).

The Table 9 shows all of the diagnosis groups detailed in Robinette et al. Table 12. For VA compensation claims up to December 1976. Again the vast majority of symptoms (apart from Nerves, and Genitourinary) are marginally significant to very significantly greater for the higher exposed FT+AT group compared to the lower exposed ET group.

Table 9: Number of men receiving VA compensation and pension, December 1976 and rates per 1000 men per year by diagnosis and exposure class, and Risk Ratio (FT+AT)/ET, Robinette et al. Table 12.

ET	FT+AT	Risk Ratio	Significance
----	-------	------------	--------------

	No.	Rate	No.	Rate	RR	95% CI	p-value
Diagnosis:							
Musculoskeletal	115	8.8	119	16.9	1.93	1.49-2.49	<0.001
Organs of special sense	49	3.7	42	6.0	1.62	1.07-2.45	0.010
Systematic conditions	3	0.2	5	0.7	3.50	0.84-14.65	0.080
Respiratory	55	4.2	51	7.3	1.74	1.19-2.55	0.001
Cardiovascular	43	3.3	47	6.7	2.03	1.34-3.07	<0.001
Digestive	74	5.7	55	7.8	1.37	0.97-1.94	0.02
Genitourinary	31	2.4	10	2.7	1.13	0.55-2.30	0.32
Skin	83	6.3	58	8.2	1.30	0.93-1.82	0.052
Endocrine	15	1.1	11	1.6	1.45	0.67-3.16	0.86
Neurological	21	1.6	16	2.3	1.44	0.75-2.76	0.29
Nerves	15	1.1	3	0.4	0.36	0.10-1.24	0.14
Mental Conditions	51	3.9	46	6.5	1.67	1.12-2.49	0.003

Except for "Nerves" all symptoms are elevated and some, as also identified by Robinette et al., are significantly and highly significantly elevated.

Discussion of Results:

This project was conducted with the objective of determining whether radar exposure to service personnel during the Korean War produced health hazards. It appears evident that the authors of the study were under pressure not to identify any adverse health effects for when they identified them, and found that they were significant, they could not bring themselves to associate them with radar exposure. Their abstract includes the conclusion:

"No adverse effects were detected in these indices that could be attributed to potential microwave radiation exposures during the period 1950-1954."

This is not true. They dichotomized individuals and occupational groups according to job matrix surveyed potential microwave exposure and found many significant increases in adverse health effects, including two significant dose-response relationships for surveyed individuals. These results are documented in their paper. The conclusion is expressed differently by Dr Silverman in a 1979 conference paper, Silverman (1979). She states:

"While some significant differences among occupational groups classified by potential exposure have been found with respect to all end points studied, the differences could not be interpreted as a direct result of microwave exposure."

Here Dr Silverman uses the term "direct radar exposure". She points out that no measures of actual as opposed to potential exposure were available. Hence occupational groups consisted of mixed exposure experiences. Dr Silverman notes the dilution effects that this produces because the high exposure AT group contained nearly 30 % of people with Hazard Number <2000, while the low exposure ET group had nearly 24 % who were in the >5000 category.

Dr Silverman is arguing that the results relate to potential and not actual exposure, which conflicts with the published paper which refuses to relate the effects even to potential

exposure. What both Dr Silverman on her own and Robinette, Silverman and Jablon together fail to recognize and appreciate are that all dilutionary influences, by their very nature, weaken the dichotomization and reduce the contrasts between exposed and control groups. These data sets are strongly influenced by several dilutionary factors.

- a. A high exposure 'repairer group' (AE), was placed in the 'operator', low exposure control group.
- b. All participants are more highly exposed to radar than the average male population of the same age, Lin et al. (1985).
- c. Combining the FT and AT groups reduces the exposure separation.
- d. All of the three 'high exposure' groups contain a mixture of low, middle and high exposure individuals.

Dilution weakens and destroys dichotomization. Hence it is remarkable and highly significant that elevated, significant, highly significant and dose-response differences still persisted through to the health statistics 20 years after the war.

After discussing this actual vs potential exposure problem, Robinette et al. (1980) stress that while considering the data about death, other disease would have been present which would not be reported:

“Further, it is possible that effects involving cardiovascular, endocrine and central nervous system do exist, but are transient, disappearing with the termination of exposure or soon thereafter, or are not perceived to be sufficiently consequential to result in admission to hospital.”

ICNIRP and the authors are wrong to conclude that this study shows no increases in cancer from radar exposure.

This study shows that exposure to radar (pulsed microwaves) results, several years later, in large, severe and highly significant health problems and death across all surveyed organs, including neurological, respiratory, endocrine, circulatory and cardiac, and cancer morbidity and mortality.

13.3 U.S. Embassy in Moscow: Lilienfeld, Tonascia, Tonascia, Libauer and Cauthen (1978). "Foreign Service Health Status Study - evaluation of health status of foreign service employees from selected eastern European posts"

13.3.1 The context:

The Soviets irradiated the U.S. Embassy in Moscow for over 20 years between 1953 and 1976 using radars. Measurements taken on the outside walls on the upper floors at which the radar was aimed showed peak exposure values of $5\mu\text{W}/\text{cm}^2$ between 1953 and May

1975, $15\mu\text{W}/\text{cm}^2$ between June 1975 and Feb 1976. After this it was a fraction of $1\mu\text{W}/\text{cm}^2$. Exposure lasted for 9hr/day in the first period and 18 hr/day subsequently. Hence for over 20 years the daily average outside exposure was $1.9\mu\text{W}/\text{cm}^2$. Inside the exposure was in the range of 10 to 50 times lower, i.e. 0.038 to $0.19\mu\text{W}/\text{cm}^2$.

The employees and dependents were studied for possible health effects from the radar exposure by a team from the John Hopkins University under the direction of highly respected epidemiologist, Professor Abraham Lilienfeld. Dr Lilienfeld noted that the group was quite small and the follow-up time too short to generally identify significant health effects such as cancer. He thus recommended that continued health status surveillance should be carried out. This was not done. The incidence of sickness and death were compare with the average US rates for similar age groups for both the Moscow Embassy and other Eastern European Embassies.

13.3.2 The key results included:

The all cause mortality rate for Moscow males as 0.42 (0.3-0.6) and for females 1.1 (0.5-1.9). Hence males, primarily State Department employees, were much healthier and females were as healthy as the average U.S. residents. This is a good example of the "healthy worker" effect. State Department selection procedures rule out a range of unhealthy people and favour healthy people.

Table 10: Sickness rates increased in Moscow with years of service: (Table 6.18)

	Under 2 yrs	2-3 years	4 + years	p-value for trend
Number of people	316	455	45	
Person-years	3709	5570	568	
Male Conditions (%)				
Present Health Summary	5.4	9.7	16.2	0.05*
Arthritis/rheumatism	4.3	6.5	8.8	0.02*
Back Pain	4.0	7.7	11.8	0.04*
Ear problems	3.8	5.6	14.7	0.02*
Vascular system	0.8	2.7	11.8	0.004**
Skin & Lymphatic	9.4	12.2	28.0	0.02*
Female Conditions (%)				
Vaginal discharge	4.2	13.8	17.5	0.04*

The sickness rates increased independent of the age at time of arrival and are increasing at a much faster rate than the influence of aging would produce.

Table 11: Neurological Symptoms per 1000 p-y, Male employees: (Table 6.31)

	Moscow	Comparison	RR	p-value
Depression	1.3	0.73	1.78	0.004**
Migraine	1.8	0.97	1.86	

Lassitude	1.2	0.78	1.54	
Irritability	1.3	0.66	1.97	0.009**
Nervous Disorders	1.5	0.64	2.34	
Difficulty in Concentrating	1.4	0.52	2.96	0.001***
Memory Loss	1.6	0.50	3.20	0.008**
Dizziness	1.2	0.85	1.41	
Finger Tremor	1.3	0.71	1.83	
Insomnia	1.1	0.90	1.22	
Neurosis	1.3	0.76	1.71	

These symptoms are consistent with the "Microwave Syndrome" of the "Radiofrequency Radiation Sickness", Johnson-Liakouris (1998). Mild et al. (1998) identified significant dose-response relationships for the following symptoms from the use of mobile phones: Memory Loss, Difficulty in Concentrating, Headache, Fatigue. Hence it is now shown and known that RF/MW exposure from extremely low but chronic exposure over many years, occupational exposure and cell phone use all produces significant and consistent neurological symptoms.

Table 12: Congenital Malformations of children after the first tour:

Conditions	Moscow SMBR	Comparison SMBR	RR	Number of children
Leukaemia and cancer	1.2	0.84	1.43	1
Blood Disorders	1.7	0.42	4.05	7
Mental, Nervous Cond ⁿ .	1.8	0.36	5.0	8
Behavioural Problems	1.4	0.68	2.06	7
Chronic Disease	1.1	0.88	1.25	7

The Risk Ratios were quite large but they were not quite significant because of the very small sample numbers.

Table 13: Blood samples showed a high proportion of the staff had significantly altered red and white blood cell counts and well above average chromosome aberrations (CA). The CA data is set out in Goldsmith (1997), i.e.

Mutagenic Level	Designator	Subjects, No.
5	Extreme	0
4	Severe	6
3.5	Intermediate	5
3	Moderate	7
2.5	Intermediate	5
2	Questionable	5
1	Normal	6

Patients with mutagenic level of 3 and above were advised not to reproduce until 6 months after somatic levels had returned to 2 or 1. This warning applied to 68 % of the patients in this sample. Staff who had elevated chromosome aberration rates were advised not to have children for until six months after they had returned to near normal.

A survey of cancer mortality rates is summarized in Table 14. This shows that despite the extremely small sample size and the very significant exposure dilution in the years between residence in Moscow and the survey results, there are highly elevated and significantly elevated rates of mortality from cancer. Lilienfeld et al. shows significantly increases chromosome aberration and cancer. This was recently also found in mice, Vijayalaxmi et al. (1997).

The dominant cancers are brain tumor and leukaemia and reproductive organ cancer. But this study, like the Korean War Study, confirms that extremely low level chronic microwave exposure is associated with very significant increases in illness and mortality in organs across the whole body, consistent with widespread cellular chromosome damage. Significantly elevated chromosome aberrations were measured in this case, Table 13, as well as significant alterations in white and red blood cell counts, Jacobson (1968). This would also be the expected result from reduced melatonin.

U.S. State Department Embassy employees are carefully selected, including physical fitness. This is one basis of the Healthy Worker effect. For these employees, including non-State Dept employees at the Embassy, their overall mortality rate was 47% of the general US population of similar ages. Their cancer mortality rate was 89%. The overall mortality rate suggests a HWE factor of 2. In Table 2 including the “employees” dilutes the health effects significantly. The employee expected mortality data were adjusted by a factor of 2 for the Healthy Worker Effect (HWE).

13.3.3 Report conclusions challenged:

It is an important principle of epidemiology, stated by both Sir Austin Bradford Hill and Dr John Goldsmith, that elevated Odds and Risk Ratios are also relevant to the public health protection basis in epidemiology, Bradford Hill (1965), Goldsmith (1992).

Professor Goldsmith was closely associated with the staff affected by the chronic radar exposure of the U.S. Embassy in Moscow and obtained information through the Official Information Act. This included the blood test results and minutes of meetings which record the fact that the State Department case officer, Dr Herbert Pollack, changed the conclusions of the final report compared with the draft report, to state that no effects could be associated with the radar exposure, Goldsmith (1997). The data and Dr Goldsmith show that this is not true. After reviewing this data, an eminent epidemiologist, Professor John Goldsmith, Goldsmith (1995), referring to a “recent draft of criteria for health protection” which claims: “No effect on life span or cause of death of 1,800 employees and 3000 dependents of the U.S. Embassy personnel”, states:

“To ignore these findings on the basis of “No effect on life span or cause of death” in setting human exposure standards is wrong. In the first place the criteria are too narrow; mortality is not the only relevant end-point. The positive or ‘findings for concern’ are ignored. Increased cancer incidence among dependents is a nontrivial endpoint.”

Table 14: Increased cancer mortality, accidents and suicide in the staff and dependents at the US Embassy in Moscow shown by data in Lilienfeld et al. (1978). This is associated with chronic extremely low intensity (distant and indoor) radar signals. "Adult" refers to adult dependant. # refers to the HWE adjustment. Note (*) p<0.05)

A highly remarkable result is the dose-response relationship for a range of sicknesses, Table 10. The results must be very highly significant to survive the exposure dilution effect with the disease gradient intact and statistically significant.

As with Robinette et al. (1980), the data presented in the Lilienfeld contract report is contrary to that stated in the report's stated (an altered) conclusions. Despite the small numbers, the lack of long latency period and dilutionary factors, the Lilienfeld data shows a significant increases in:

- Cardiac symptoms
- Neurological and psychological symptoms
- Altered blood cell counts
- Increased chromosome aberrations, and
- Elevated cancer in children and adults
- Sickness increasing in a dose-response manner with years of residence.

These symptoms are associated with chronic exposure to very low intensity pulsed microwaves in the range < 0.1 to $1\mu\text{W}/\text{cm}^2$.

In a sense too, the fact that the State Department case officer, Dr Herbert Pollack, altered the conclusions, attests to the significance of this study, the results of which would be embarrassing to the U.S. Government, both in terms of compensation and in terms of the validity of the U.S. exposure standard.

13.4 Selvin et al. (1992): "Distance and risk measurements for the analysis of spatial data: a study of childhood cancer" - The Sutra Tower Study, San Francisco.

13.4.1 Background:

Selvin et al. (1992) is widely quoted in national and international reviews as showing no evidence of health effects from a powerful telecommunications tower near a human population. The ICNIRP (1998) statement is typical when it says: "Selvin et al. (1992) reported no increase in cancer risk among children chronically exposed to microwaves radiation from a large microwave transmitter near their homes."

13.4.2 Broadcast tower residential exposure patterns:

Selvin et al. (1992) made a major error by assuming that the public exposure varies linearly with distance from the tower. Their conclusions were firmly based on this assumption and therefore are wrong. Radio engineers know a great deal about broadcast antennae radiation patterns. Some typical VHF examples are given in section 1.9 and Figures 4 to 6. The ground level radial pattern shows a complex of undulating patterns whose peaks and troughs vary with the wavelength of the signals and the height of the antennae. The transmissions from the Sutra Tower have weak VHF and powerful UHF signals. Figure 20 shows a typical UHF signal taken from an antenna vertical pattern in Hammett and Edison (1997).

Figure 20: Ground level exposure for a typical UHF TV broadcast signal, from an antenna pattern from Hammett and Edison (1997), for a 2.4 MW ERP transmitter at 400m AGL, for a flat surface.

Figure 20 shows that the strongest peaks for UHF signals occur between 2 and 4 km, and the main beam peaks outside 10 km, around 11 to 15 km from the base of the tower. Measurements taken around the Sutra Tower are presented in Figure 21, showing the mix of VHF and UHF broadcast stations.

Figure 21: The measured and estimated power density (exposure in $\mu\text{W}/\text{cm}^2$) with distance from the Sutra Tower. Circles show measurements. The line follows measurement points and the radial pattern of Figure 20 beyond 3 km. From Hammett and Edison (1997) and readings taken by the author in 1999.

The high peak close to the tower and the peak near 1 km are from the VHF (FM radio) transmissions, as shown in Figure 5. The peaks outside 2 km are primarily UHF signals, as shown in Figure 20.

13.4.3 Residential Exposure Factor:

The direct exposure measurements or calculations need to be adjusted for epidemiological purposes because people largely live inside and move around a great deal. The mean Personal exposure Factor has (PEF) has been estimated as 0.15, Section 1.10. For example, the measured outside signal at the five homes of the children who live within 1 km of the tower and who have brain tumour, averages $1.74\mu\text{W}/\text{cm}^2$. When the PEF of 0.01 is applied this becomes $0.02\mu\text{W}/\text{cm}^2$.

13.4.4 The objective of Selvin et al.:

In an email Prof Steve Selvin acknowledges that the study was not an epidemiological study. Selvin et al. were concerned with developing statistical data analysis techniques involved in comparing spatial clustering with risk approach to data analysis of potential effects from point sources of exposure. They apply their methods to the white, childhood cancer data for children <21 years living in the vicinity of the Sutra Tower to test the presence of clustering. An example, of the spatial distribution for childhood leukaemia, is given in Figure 22.

Figure 22: Spatial map of white childhood (<21 years) leukaemia for San Francisco, 1973-88, from Selvin et al. (1992).

13.4.5 The results and errors in Selvin et al.:

Selvin et al. were totally unaware of the reality of radiation patterns and simply assumed that exposure varied linearly with radial distance. This was used to test three method of statistical clustering in an attempt to define the exposed vs unexposed populations. These approaches showed that peak cancer rates occurred at a radius of 1.75 km from the tower. From their methods this defines the exposed group to be within twice this distance, i.e. within 3.5 km. Because they assumed a linear decline in exposure with distance from the tower they conclude: "None of the three analytic approaches indicates the presence of

clustering of childhood cancers associated with the Sutra Tower.” If they knew the actual radial radiation pattern then their conclusion would have been very different. They also placed the tower about 1km too far to the west.

13.4.6 Detailed spatial cancer incidence and exposure analysis:

Childhood cancer rates and residential locations are given for the period 1973-1988 by Selvin et al. (1992). A total of 123 cases of cancer were identified among 50,686 white individuals at risk under the age of 21 years. These included 51 cases of leukaemia, 35 cases of brain tumour and 37 cases of lymphatic cancer. Selvin et al. estimate that these categories of cancer cover close to 50 % of all cancers. Each childhood leukaemia case is given a residential location on a spatial map, Figure 16.

It is immediately evident in Figure 22 that there are higher childhood leukaemia rates in the eastern sector compared to the western, northern and southern sectors. Antenna radiation patterns and model calculations for all the antennae on the Sutra Tower, are given by Hammett and Edison (1997). These show that readings and model calculations give highest radiation intensities in the eastern sector. The broadcasters aim their signals at the greatest population in the city and across the Bay in Oakland and Berkeley. This is the first indication of a dose-response relationship.

Figure 22 also reveals the lack of cancer and residence in Golden Gate Park to the WNW of the tower, the broad low density housing area of the Army Base, the Presidio to the NW, a large park area and hills to shade suburbs to the SW, the Central business district to the ENE and the port and industrial area along the eastern coastline. These were all taken into account when the residential population density was calculated below. The cluster 48-51, to the NE are residences on a western facing hill slope, with higher exposure levels from the Sutra Tower than the radial distance implies. They contribute to the higher cancer rate in the >5km km ring compared with the 4-5km ring. This explains some of the scatter about the dose response line.

Results:

Close to Tower Childhood Cancer Rates:

The spatial cancer map, Figure 1, shows some circular patterns of high and low cancer rates and a high cancer rate in the immediate vicinity to the tower, <1 km. Within 500m of the tower there are 2 Brain Cancer cases, Table 3. Compared with the Brain Cancer rate in the very low exposure group (>5 km), this results in:

$$RR = 64.2, 95\%CI: 10.8-382, p=0.00103$$

The first 0.5km ring with at least one case of each cancer type is 0.5-1km. The cancer rates in the <1.0km ring are in Table 15.

Table 15: The Near Sutra Tower (<1km) Childhood Cancer rates compared with the remote >5km rates. (* Fisher Exact p-value for n<5).

Cancer Type	Cases	RR	95%CI	p-value
Brain Cancer	3	15.5	3.14-76.8	0.004*
Leukaemia	2	5.2	1.05-25.6	0.08*

Lymphoma	2	15.5	2.19-110	0.02*
Leukaemia/Lymphoma	4	7.8	2.34-25.7	0.0045*
All Cancer	7	9.9	3.84-25.4	<0.0000001

All cancer types are significantly elevated, except the lowest, Leukaemia, RR = 5.2, 95%CI: 1.05-25.6, n=2. For All Cancer the RR = 9.9, 95%CI 3.84-25.4, $p < 0.0000001$. Brain Cancer (RR = 15.5) and Lymphoma (RR=15.5) are highly significantly elevated. The strength of the relationship of the All Cancer is classically causal, Hill (45). This occurs despite the very small sample size but the strength of the relationship is supported by several previous studies showing elevated cancer rates around broadcast towers.

Broad Ring (1km) Analysis:

The data set out in Table 3 was grouped into 1km rings out to 5km, with the cancer rates compared to the rates in the >5km remote ring, Table 16.

Table 16: The broad ring trend analysis with distance from the Sutro Tower, with Childhood Cancer rates relative to the remote >5km ring. The brackets show p-value adjusted for the single low data outlier.

Ring km	Brain Cancer		Leukaemia		Lymphoma		All Cancer	
	RR	95%CI	RR	95%CI	RR	95%CI	RR	95%CI
0.1-1	15.5	3.14-76.8	5.2	1.05-25.6	15.5	3.19-110	9.9	3.84-25.4
1-2	7.8	2.1-30.9	7.2	3.07-20.8	3.4	0.48-24.3	7.2	3.45-14.7
2-3	3.3	0.84-13.4	3.3	1.25-8.9	11.0	2.48-48.6	4.7	2.37-9.35
3-4	3.2	0.85-12.1	1.8	0.64-5.1	6.6	1.47-29.9	3.1	1.53-6.17
4-5	3.07	0.81-11.6	1.5	0.53-4.4	4.0	0.84-19.4	2.41	1.17-4.93
>5	1.00		1.00		1.00		1.00	
Trend p-value	0.03		0.02 (<0.005)		0.08 (<0.001)		<0.001	
Log/Lin Trend	p<0.001		0.05 (<0.03)		0.07 (<0.02)		<0.0001	

Table 16 shows significantly elevated childhood cancer rates in all 1km rings for All Cancer. For Brain Cancer all rates are significantly elevated for <2km and with a consistently declining with a significant linear trend, $p=0.03$, and highly significant log-linear trend, $p=<0.001$. Leukaemia and Lymphoma rates show quite variable patterns, especially for the small samples in ring <1km for Leukaemia and out to 2km for Lymphoma. They both show significant linear and log-linear trends, especially when the small sample outliers are removed. When all the data is combined to form the All Cancer trend, it is significantly elevated in all 1km rings and consistently declines with distance. There is also a highly significant linear trend, $p=0.001$, and a log-linear trend, $p=0.0001$, Figure 23a.

Exposure related dose-response graphs are shown in Figures 23b and 23c. These observations, through their strength of association, the level of significance and the dose-response relationships, especially for All Cancer, give considerable support to the hypothesis of an association between RF/MW exposure and cancer risk.

The trend line was fitted to ignore the outlier. The low exposure outlier near $0.7\mu\text{W}/\text{cm}^2$ contains a very small population of Leukaemia/ Lymphoma cases. When it is removed

then the trend has $p < 0.00001$. The Brain Cancer RF/MW exposure trend is extremely significant, $p < 0.00001$, Figure 23b.

Figure 23a: All Cancer around the Sutro Tower in a 1 km radial ring pattern, Log-Linear Trend $p < 0.0001$.

Figure 23b: All Childhood Cancer as a function of measured and estimated RF/MW exposure in 0.5 km radial rings, ignoring the 9 $\mu\text{W}/\text{cm}^2$ outlier that only contained Brain Cancer. Trend $p < 0.0001$.

Figure 23c: Childhood Brain Cancer as a function of measured and estimated RF/MW exposure in 0.5 km radial rings. Trend $p < 0.00001$.

This analysis shows that a fairly realistic approach accepts that the radial RF/MW radiation and cancer patterns vary in a logarithmic fashion with distance from the tower. This produces a linear exposure-based dose-response trend for cancer rates, from logarithmic distance-based, exponential cancer rates, found in San Francisco and around the Vatican Radio Towers outside Rome, Michelozzi et al. (2002), Figure 23e.

Figure 23e: Cumulative childhood leukaemia near the Vatican Rome Radio Station with an exponential fitted trend line, $R^2 = 0.9756$, $p = 0.002$, Michelozzi et al. (2002).

The logarithmic/exponential radial cancer rates are appropriate for sites with powerful VHF antennas, which are on the Sutro Tower and on the Vatican Radio Towers.

The exposures used are the measured and estimated direct exposures. The actual chronic mean personal exposures are highly probably less than 1-2% of the direct exposure because of the shadow effects and household protection effects. All of the dose-response relationships are extremely significant and support the hypothesis that RF/MW is a Universal Genotoxic Carcinogen increasing the incidence of multiple cancer types with no safe threshold level.

Contrary to the conclusion of Selvin et al. and ICNIRP (1998), who claim that this study shows no evidence of adverse effects, the spatial data when related to actual radial radiation exposure patterns forms significant linear dose-response relationships, with All Cancer and Brain Tumour having extremely significant dose-response relationships.

This results in the data in Selvin et al. (1992) show a very highly significant dose response relationships which, when combined with other epidemiological studies, shows a causal relationship between RF/MW exposure and several childhood cancers, especially brain tumours, leukaemia, Hodgkin Lymphoma and all cancer.

13.5 Beall, Delzell, Cole and Brill (1996) "Brain Tumor among Electronics Industry Workers:

ICNIRP (1998) claims that this study showed no significant increases in nervous system tumours. This is factually wrong. The overall results of Beall et al. (1996), as presented in their abstract is: There was elevated ORs:

“For 10 or more years of employment in engineering/ technical jobs (OR = 1.7, 95% CI: 1.0-3.0) or in programming jobs (OR = 2.8, 95% CI: 1.1-7.0). The OR for glioma for all subjects who had accrued 5 years of programming work 10 years before the case’s death was 3.9 (95% CI: 1.2-12.4).”

These are statistically significant relationships. The subjects were chosen and studied because of the possibility and concern that using VDTs (Visual Display Terminals, i.e. computers) a great deal in their occupations. VDTs expose workers to a wide range of EMR for long periods, could be related to the increase in brain tumours. The researchers found differences between different occupations who use VDTs in different ways.

For example, those in manufacturing of VDTs they found OR = 0.8, while those in manufacturing VDTs who also used them for programming, OR = 1.5 (95%CI: 0.8-2.7) and those in manufacturing VDTs who used them for information, OR = 1.3 (95%CI: 0.4-4.1).

Odd ratios for brain tumours increased with the longer times in jobs using VDTs. After 10 years the engineering/technical jobs had an OR = 1.7 (95%CI: 1.0-3.0) and programming, OR = 2.8 (95% CI: 1.1-7.0). These show dose response relationships, Figure 24.

Figure 24: Dose-response relationships for brain tumor mortality from Table 3 in Beall et al. (1996). These show linear dose-response relationships with years of using computers with the complex EMR exposure from the VDT.

This study shows that the particular groups which use live computers regularly have elevated Odds Ratios (increased levels of risk of brain tumour), and significant increases after 10 years of service. For computer programmers it is significant, $p=0.04$. The overall analysis, Figure 25, comparing gliomas and all brain tumours, men, women and total groups all show dose-response relationships but the relationship is not assessed as statistically significant:

Figure 25: Dose-response relationships for all brain tumors and Glioma for years of using VDTs.

The sample of men is somewhat larger than that for women. Men show increasing risk of all brain tumours and gliomas with the increasing work time with VDTs but women only show an increase in the 10-19 year group. Only 4 women are in the ≥20yr-group. There is a good evident reason for this. Women's employment is not usually as long as men in these jobs.

Exposures to EMR from VDTs has decreased over the decades with the introduction of low radiation" monitors. Measured RF/MW exposures at the head level of a computer user, 0.5 m from the screen, have been measured at 0.1 to 5 μ W/cm². Using a mean lifetime exposure factor of 0.25, based on 0.3 for the time at/away from work and 0.8 for the time programmers are at/away from the computer of 0.8, gives an estimated average lifetime exposure in the range 0.025 to 1.25 μ W/cm². The range is of the same order of mean lifetime residential exposure for the children in San Francisco who had a very significant increase in brain tumour and other cancers with a dose-response relationship.

Beall et al. (1996) does show statistically significantly increases of brain tumours for those using VDTs in their work for more than a 2 decades. Several relationships also showed dose response increases with brain tumours with longer periods of employment using VDTs, though the small sample sizes limit the statistical significance, these are indicative of probable relationship. The study is misrepresented by the ICNIRP reviewers as a study which shows no effects.

13.6 Grayson (1996) : "Radiation Exposure, Socioeconomic Status, and Brain Tumor Risk in the U.S. Air Force: A nested Case-Control Study".

13.6.1 The ICNIRP claim:

Once more the ICNIRP (1998) paper claims that this paper "failed to show significant increases in nervous tumors". Grayson actually shows the opposite conclusion.

13.6.2 The Context of this Study:

Grayson acknowledges that EMFs are generally considered to be able to promote cancer by interfering with intercellular communications but that Balcer-Kubiczek and Harrison have observed that microwaves may act alone as tumor initiators or as cocarcinogens. He also reviews several other epidemiological studies which support the association between RF/MW exposure and brain tumors. Eighteen such studies have been identified by the present author. Grayson cites Thomas et al. (1987) who found a significant dose-response relationship for Astrocytoma, the most common form of brain tumour, and years of service in the electronics industry, with a co-carcinogenic relationship with lead from solder fumes. The RF/MW exposure had the greater effect.

A study published earlier in 1996, Grayson and Lyons (1996) investigated the incidence of cancer in United States Air Force Aircrew. Aircrew are moderately exposed to ELF and RF/MW during their flight times and on bases. Grayson and Lyons found that Aircrew had significantly higher cancer rates than other USAF officers, RR = 1.31 (95%CI: 1.11-1.54, n=342). For brain tumor the incidence was elevated, RR = 1.20 (95%CI: 0.52-2.78, n=13), but not significantly so, largely because of the small case sample size (n). For other cancers, cancer of the testes and urinary bladder were significantly elevated.

Grayson notes that EMF (ELF) studies generally found negative results or suggest a small excess risk. Sahl, Kelsh and Greenland (1993), Tynes, Jynge and Vistnes (1994) found no increase in brain tumor in electric utility or railway workers. Theriault et al. (1994) found an elevated risk (OR = 1.95, 95%CI: 0.76-5.00) and Floderous et al. (1993) a significantly increased risk (OR= 1.5, 95%CI: 1.0-2.2) in electrical workers.

Mack, Preston-Martin And Peters (1991), Speers et al. (1988) and Loomis and Savitz (1990) found highly significant increases; and Lin et al. (1985), Thomas et al. (1987), Preston Martin, Mack and Henderson (1989) found significant dose-response relationships for increased brain tumors in EMR exposed populations.

Using the EMR Spectrum Principle, this amounts to very strong evidence which is indicative of a causal relationship.

11.6.3 Grayson's results:

Grayson carried out a job title-time-exposure matrix utilising potential intensity scores for both ELF and RF/MW EMR exposures. Data on ionizing radiation exposure was also available.

“Although the present study has its limitations, particularly in exposure estimation, it does suggest that there is a small association between potential EMF exposures and brain tumor risk among Air Force members, especially for personnel potentially exposed to Radiofrequency/microwave EMFs.”

The results for the three types of radiation exposure, after adjustment for: Age-race-senior military rank, were:

Ionizing Radiation	OR = 0.58	95%CI: 0.22-1.52
ELF Radiation	OR = 1.28	95%CI: 0.95-1.74
RF/MW radiation	OR = 1.39*	95%CI: 1.01-1.90

The relationship for age-race adjusted Odds Ratios for rank were:

Rank	OR = 2.11**	95%CI: 1.48-3.01
Senior Rank	OR = 3.30**	95%CI: 1.99-5.45

The ELF and RF/MW exposure results are consistent with the second part of the EMR Spectrum Principle, that there are likely to be stronger effects at higher frequencies. These results are consistent with and confirming of the studies cited above, section 11.6.2.

The rank-related results are independent of the exposure-related results. They raise the question of the influence of socio-economic status, which is accurately represented by military rank. Preston Martin (1989) and Preston-Martin et al. (1993) also find that brain tumour risk increases with socio-economic status.

Grayson (1996) is far from a “no effects” study. Thus far consistently the ICNIRP claims are scientifically wrong and misleading. This study does show a small but statistically significant increase in brain tumour from RF/MW exposure.

11.7 Rothman, Chou, Morgan, Balzano, Guy, Funch, Preston-Martin, Mandel, Seffens and Carlo (1996): Assessment of Cellular Telephone and Other Radiofrequency Exposure for Epidemiologic Research, and

11.7.1 The Context:

This and the next paper, Rothman (1996 a and b), are used to imply that there is "no excess total mortality was apparent among uses of mobile phones". This is on the ICNIRP context of citing papers, as the six above are quoted, claiming that they show no increases or no significant increases in brain tumour or cancer. This paper, Rothman et al. (1996a), is the description of an epidemiological study in progress about the potential association of mobile phone use and brain tumour.

11.7.2 The Conclusion:

ICNIRP's follow up statement is actually true: "but it is still too early to observe an effect on cancer incidence or mortality". The latencies of brain tumours is decades. This is not an appropriate paper to cite in a cancer assessment because it has no evidence value for or against the incidence of cancer in RF/MW exposure.

11.8 Rothman, Loughlin, Funch and Dreyer (1996): “Overall Mortality of Cellular Telephone Customers”

This a study compared the rates of mortality between mobile phone users and portable phone users. For the cancer latency reasons above it is a very preliminary report. The authors state that the present preliminary findings have two major limitations:

“First, they do not directly address the issue of the relationship between cellular telephone use and brain cancer, which comprises only a small proportion of deaths. Second, the time between exposure to radio frequency energy from portable cellular telephones and the death endpoints that we measured was comparatively short, and our study therefore addresses only short-term effects.”

Therefore, in the context of a cancer assessment, this too is a totally inappropriate paper to include in this assessment for it does not and cannot add evidence to the assessment.

11.9 Interim Conclusions (Papers 1 - 8.):

All of the first 8 papers or reports cited by ICNIRP with the clear intention of dismissing the possibility of cancer being related to RF/MW exposure. All are inappropriately or incorrectly cited. In some cases they are deliberately, misquoted and misused. In reality the reverse of what ICNIRP claims is true.

Three of the papers, Barron and Baraff (1958) and Rothman et al. (1996 a,b) are inappropriately included when they are not giving epidemiological results of cancer resulting from RF/MW exposure.

The remaining five reports or papers all show statistically significant increases in cancer of various body organs, especially brain tumour and leukaemia. Three of them also show significant dose-response relationships for a range of cancer, including respiratory cancer, Robinette et al.; Brain Tumour, Leukaemia, Hodgkins and Non-Hodgkin's Lymphoma and All Cancer, Selvin et al., and Brain Tumour, Beall et al..

Two show these results with extremely low mean residential RF/MW exposures, one moderate to low exposures from computer screens and two moderate to high exposures from military radio and radar radiation. The residential study shows that statistically significant increases in childhood cancer occur in a dose-response manner. For ALL Cancer, Selvin et al.(1992), the threshold is close to zero, about $0.02\mu\text{W}/\text{cm}^2$. The results of my reanalysis Sutro Tower study is confirmed by the Vatican Tower study. My re-interpretation of the UK studies, Dolk et al. (1997a,b) has been published, Cherry (2001) in the American journal of epidemiology in which by comparing the population patterns and see radial radiofrequency radiation patterns a explaining the strong relationships between the radiofrequency exposure in the radial cancer rates. My published conclusion is that the results of these UK studies is indicative of a causal relationship.

12. Studies that are acknowledged by ICNIRP to show increases in cancer from RF/MW exposure:

There are five papers covering three studies. Szmigielski et al. (1988) and Szmigielski (1996) cover the Polish Military Study, Dolk et al. (1997a and b) cover the U.K. Regional TV Tower Study and Hocking et al. cover the North Sydney Broadcast Tower Study.

12.1 The Polish Military Study:

Szmigielski, Bielec, Lipski and Sokolska (1988) "Immunologic and Cancer-Related Aspects of Exposure to Low-Level Microwave and Radiofrequency Fields", and Szmigielski (1996) "Cancer morbidity in subjects occupationally exposed to high frequency (radiofrequency and microwave) electromagnetic radiation".

12.1.1 ICNIRP Dismissal:

ICNIRP's complete, comprehensive and in-depth assessment of this project is fully quoted in the following two sentences:

"There has been a report of increased cancer among military personnel (Szmigielski et al. (1988)), but the results of the study are difficult to interpret because neither the size of the population nor the exposure levels are clearly stated. In a later study, Szmigielski (1996) found increased rates of leukaemia and lymphoma among military personnel exposed to EMF fields, but the assessment of EMR exposure was not well defined."

This is a woefully inadequate and thoroughly unprofessional treatment of this large epidemiological study. The ICNIRP response represents a total misunderstanding or misrepresentation of epidemiology.

12.1.2 Cancer Epidemiology:

Most cancer studies are based on using records from cancer registers over several decades because it takes decades for cancer to develop and large populations are necessary for statistical quality and significance. Retrospective studies, such as cohort and case control studies rarely, have records of the hourly or daily mean exposure of every participant for the period of the register. Hence occupational activities involving exposure to a potential disease agent is the most common surrogate for exposure. Sometimes a job exposure matrix assessment is undertaken of a typical sample of tasks involved in a job. This improves the exposure assessment but it remains an estimate of potential or probable exposure. Because of these practical limitations epidemiology is based on careful selection of occupational groups in order to compare morbidity and mortality rates between exposed and non-exposed or low exposure control groups.

Hence many studies involve "electrical occupations", "power station workers", "electric train drivers", "electric utility workers", "computer programmers", "sewing machine operators", "TV repairmen", etc... Their cancer and illness rates are then compared with a set of controls who are selected because they have the same age-race-income-geographic- ... characteristics to make them as similar as possible to the exposed people with the one exception of the exposure. Years of service become a reasonable estimate of cumulative exposure and thus a source of a dose-response gradient. For some

occupations the EMR exposures are intermittent and associated with a particular activity. For example, physiotherapists using RF/MW heating for diathermy prior to muscular manipulation. These exposures are generally for only a minute or two after the machine has been turned on. The monthly number of treatments is a good measure of the cumulative monthly dose or the monthly mean exposure.

12.1.3 Polish Military Exposure Assessment:

Thus, most EMR epidemiological studies rely solely on occupational descriptions as a surrogate for exposure. Refinements include job exposure matrix surveys or reported exposure incidents. In this latter case any exposure radiation from an active radio antenna or radar antenna is reported and recorded, along with the estimated level of exposure and time of exposure. This is because strict daily limits are maintained based on cumulative dose. This is the EMR Hygiene reporting regime. It has been used in the Polish Military since about 1968. Hence the Polish Military Study uses one of the more advanced exposure assessment regimes of any study published. Szmigielski (1996) states:

"Data on exposure of personnel to RF/MW were collected from EM military safety groups operating as health hygienic services. These groups are responsible for measurements of RF/MW field intensities at and around service posts where EM emitting equipment is used, repaired or serviced, and keep health records of personnel working on these posts. The number of personnel considered to have been exposed occupationally to RF/MW was easily established, but the evaluation of the exposure rate appeared to be quite difficult."

Thus to be considered as a member of the exposed group, exposure episodes were required to be recorded. All other personnel are used as controls. This is one of the most advanced exposed group selection criteria ever used.

12.1.4 Population Description:

The data set used by Szmigielski et al. was 1971-80, and Szmigielski (1996) updated this to use 1971-85. Szmigielski et al. state:

"The total population of career servicemen (in the Polish armed forces) was analyzed, and a subgroup of personnel exposed occupationally to MW/RF radiation (on the basis of service records) was developed; the E (exposed) group counted about 3 % of the total population, the rest (97%) was considered as subjects without exposure to MW/RFs (the NE group)."

Szmigielski (1996), it is explained that over the 15 years there is a slight year to year variation in the population but it averages 128,000 person each year with 3700 MW/RF being exposed. The data set is somewhat larger than that used by Robinette et al. (1980). Over the 15 year data set there are 1.92 million person-years in the control group and 55,500 p-yrs in the RF/MW exposed group.

Thus the Polish Military study is a very large study with a well defined population with a high quality criteria for identifying the exposed vs control groups. ICNIRP is wrong in its criticism and wrong to dismiss this highly significant study.

12.1.5 The Results of Szmigielski et al. (1988)

12.1.5.1 Health Effects Assessment:

Szmigielski et al. are acutely aware that evidence of immunological impairment with RF/MW exposure is evidence of increased cancer risk since the immune system is a vital part of the cellular repair mechanism of our bodies. Hence they first review evidence that RF/MW impairs the immune systems in cells and animals.

12.1.5.2 Cell line (*In Vitro*) studies:

They found and present evidence of immunosuppression and immunostimulation associated with RF/MW exposure of cells to a wide range of frequencies, modulations and intensities. This is related to the hypothesis of Professor Ross Adey and his group about the modification of calcium ion binding at the cell membrane surface, and its flow on effects into the signal transduction regulation of the cells. We are now aware that both calcium ion efflux and influx occur at different combinations of RF/MW signal impacting on the cell membrane. This is consistent with immunosuppression and stimulation respectively.

12.1.5.3 Whole animal (*In Vivo*) Studies:

Short-term exposures of experimental animals to low level RF/MW initially confused thermal effects with non-thermal effects. Careful control of exposure and better handling of animals found consistent transient and reversible increase lymphocyte proliferation and function. However, that time there was not convincing *in vivo* evidence of immune system impairment from short-term RF/MW exposure, and, at that time “There are no experiments *in vivo* involving exposure of animals to low-frequency modulated MW with examination of the immune functions. On the other hand, as discussed below, both the higher susceptibility of animals to chronically exposed bacterial and viral diseases, and the data on acceleration of development of neoplasms in mice exposed for months in non-thermal MW fields (the two phenomena that might result from suppression of immune functions in chronically exposed subjects) emphasize the problem of the response to long-term low-level irradiation in MW/RF fields, and they call for further investigation.”

However, Szmigielski et al. appear to be unaware of Shandala et al. (1983) which did find a highly significant (78%) and persistent suppression of the immune system rats when exposed to 500 $\mu\text{W}/\text{cm}^2$ for 3 months.

12.1.5.4 Integrated evaluation of immunity in MW/RF exposed animals:

Szmigielski et al. proceed to describe their own experiments in this area. They conclude:

“An overview of the available and of our own findings suggests the existence of a biphasic reaction of the immune system to MW/RF radiations - stimulation of the whole system (mainly humoral immunity) after a single or few days exposures, followed by gradual, but transient, suppression of the whole immunity with prolongation of the exposure period (up to several months) and/or increasing power density of the fields. Stimulation and suppression of immunity in MW/RF exposed animals both seem to be transient and

inconsistent phenomena. At low power densities the system recovers soon after exposure.”

This raises the question, what happens if exposure continues for years?

12.1.5.5 Cancer related aspects of exposure to low-level microwave fields:

Human populations contain a wide range of people, including those with already compromised immune systems. The evidence that chronic exposure of animals can suppress their immune system with some combinations of parameters of low-level microwave exposure promoted the study of the effects of MW exposure on cancer prone mice. This was a precursor for looking for cancer in MW exposed human populations.

Szmigielski et al. planted cancer cell in the lungs and on the skin of mice and chronically exposed them to non-thermal intensities of 2.45 GHz microwaves. The tumors grew faster and the mice died earlier in the exposed compared to the sham exposed mice. The MW exposed mice with induced skin cancer showed 50 % died after 137 days, compared to 305 days for the sham exposed mice. The lung tumors which all started at near 2×10^5 viable cells. After 3 months, the control group stayed close to 2×10^5 , while the exposed mice rose to 6 and 15 for 5 and 15 mW/cm² respectively.

They then showed that microwaves on their own and with a cancer promoter, significantly enhanced cyclic AMP activity in urine epidermis (scraped) samples in mice.

They concluded:

“On the basis of Balcer-Kubiczek and Harrison’s reports, and the above investigations of his own group, Adey (personal communication) recently offered his own concept and initial model of the cancer-promotion process and its influence by MW/RF fields modulated at low frequencies. The promotion appears to relate to a distorted inward stream of signals from the cell membrane to the nucleus (where carcinogenesis was already initiated by other factors) and to intracellular organelles. MW/RF modulated at low frequencies may in certain cases (depending upon modulation and time exposure) act synergistically with the action of promoters, activating the same membrane receptors.”

Hence, prior to presenting their human study of cancer in MW exposed military personnel, Szmigielski et al. outline a strong evidence trail indicating the probability of cancer being found based on cellular and animal experiments, based on immune system impairment, and synergistic activity of RF/MW with other cancer initiators and promoters.

12.1.6 Polish Military Study (1971-80):

Placing the study in context, the authors note several previously published studies showing increases cancer (McLaughlin (1953)), in leukaemia with radar exposure (Lester and Moore (1982)), Milham (1982) and Wright (1982), and Vagero and Olin (1983).

They note that Robinette et al. (1980), the Korean War Study, reported no significant differences between high and low exposure groups, but point out:

“However, when three sub-groups of the high-exposure group were developed to provide a gradient of potential exposure, a trend appeared for increased number of malignant neoplasms in the sub-group rated as highly exposed.”

They also refer to weakness of the Korean War study in terms of its size and subject selection. They don't investigate the Korean War Study data in depth as is done here.

The preliminary results of the Polish Military Study, using the 1971-80 data set, is presented in Figure 26 and 26a.

Figure 26: Cumulative yearly morbidity rate of neoplasms during 1971-80 (expressed as the number of new cases per 100,000 person years) for all ages (20-59 years) in MW/RF exposed subjects and non-exposed subjects. Top histogram show organ localization of malignancies for oral cavity; pharynx and larynx; esophagus and stomach; colo-rectal, liver and pancreas; lungs; bones; skin including melanoma; kidneys-urogenital tract- prostate; eyes and central nervous system; thyroid gland and other endocrine glands; hematopoietic and lymphatic organs.

The high incidence of cancer of the hemato-lymphatic organs allows the break down given in the lower half of the diagram. LGR: malignant lymphogranulomatosis; LS, LM, lymphosarcomas and lymphomas; CLL, chronic lymphatic leukemia; ALL, acute lymphoblastic leukemia; CML, chronic myelocytic leukemia; AML, acute myeloblastic leukemia and PL, plasmocytoma (plasma cell leukemia).

This data shows that the microwave exposed group, compared to the low exposure group, had increased malignancies in every category of organ, significantly increased in esophagus and stomach, colo-rectum, skin cancer including melanoma and thyroid, and highly significant in blood and lymph organs. Individual leukemia's which were significant were Acute Myeloblastic leukaemia and highly significant were chronic myelocytic leukaemia and lymphosarcomas and lymphomas.

The decadal age category results are presented in Figure 26a.

Figure 26a: Cancer morbidity rates in RF/MW exposed and “non-exposed” personnel for all types of malignancies at various age groups.

Note the largest differences at the age group 40-49 years and statistical significance of differences for all age groups. The Chi Squared values indicate that the differences are much more significant than $p < 0.01$. All of those identified at $p < 0.01$ are actually $p < 0.001$. This analysis shows that RF/MW exposure initiates earlier cancer and accelerates it in the middle decades.

12.1.7 Polish Military Study (1971-85):

Szmigielski (1996) is a follow-up study from the previous study, adding a further 5 years of morbidity data. With the larger data set the significance of the observed increases in cancer are increased. The data is summarised in three tables, in parallel with the summary diagrams of Szmigielski et al. (1988) above, showing morbidity of body organs, haemopoietic malignancies and age-grouped relationships.

Table 15: Incidence of neoplasms (per 100,000 subjects annually) in military personnel exposed and non-exposed (control) to radiofrequency and microwave radiation, Szmigielski (1996).

Localization of malignancies	Incidence (Expected)	Incidence (Exposed)	Risk Ratio	95% CI interval	p-value
Pharynx	1.96	2.12	1.08	0.82-1.24	N.S.
Esophageal and stomach	4.83	15.64	3.24	1.85-5.06	<0.01
Colorectal	3.96	12.65	3.19	1.54-6.18	<0.01
Liver, pancreas	2.43	3.58	1.47	0.76-3.02	N.S.
Laryngeal, lung	21.89	23.26	1.06	0.72-1.56	N.S.
Skin, including melanomas	3.28	5.46	1.67	0.92-4.13	<0.05
Nervous system including brain tumour	2.28	4.36	1.91	1.08-3.47	<0.05
Thyroid	1.38	2.12	1.54	0.82-2.59	N.S.
Haematopoietic system and lymphatic organs	6.83	43.12	6.31	3.12-14.32	<0.001
All malignancies	57.60	119.12	2.07	1.12-3.58	<0.05

As in the 1988 analysis, this data shows that RF/MW exposure increases cancer across the body with elevated Risk Ratios, and several organs show significantly and very significantly higher cancer rates, including Esophageal and stomach cancer, Colorectal cancer, Skin cancer, Brain and CNS cancer and all malignancies. The Haematopoietic and Lymphatic cancers are very highly significantly elevated and so are separated further in Table 16.

Table 16: Incidence of haemopoietic and lymphatic malignancies (per 100,000 subjects annually) in military personnel exposed and non-exposed (control) to radiofrequency and microwave radiation.

Localization of malignancies	Incidence (Expected)	Incidence (Exposed)	Risk Ratio	95% CI interval	p-value
Hodgkin's disease	1.73	5.12	2.96	1.32 - 4.37	<0.05
Lymphoma (non-Hodgkin and lymphosarcoma)	1.82	10.65	5.82	2.11 - 9.74	<0.001
Chronic lymphocytic leukaemia	1.37	5.04	3.68	1.45 - 5.18	<0.01
Acute lymphoblastic leukaemia	0.32	1.84	5.75	1.22 - 18.16	<0.05
Chronic myelocytic leukaemia	0.88	12.23	13.90	6.72 - 22.12	<0.001
Acute myeloblastic leukaemia	0.71	6.12	8.62	3.54 - 13.67	<0.001
Total	6.83	43.12	6.31	3.12 - 14.32	<0.001

In the 1988 data analysis, three sub-categories of leukaemia and lymphoma were significantly increased with RF/MW exposure. In this larger data set all are significantly increased and 4 are very highly significantly increased, Lymphoma, Chronic Myelocytic Leukaemia, Acute Myeloblastic Leukaemia and Total leukaemia/lymphoma. The age-group relationships show the same initiation and advancement of the cancer rate in the exposed group.

Table 17: Incidence of neoplasms (tumors) (per 100,000 subjects annually) in age groups of military personnel exposed and non-exposed (control) to radiofrequency and microwave radiation, Szmigielski (1996).

All sites:

Age Group	Incidence (Expected)	Incidence (Exposed)	Risk Ratio	95% Conf. interval	p-value
20-29	11.62	21.11	2.33	1.23 - 3.12	<0.05
30-39	18.37	42.28	2.30	1.04 - 3.06	<0.05
40-49	84.29	161.62	1.92	0.98 - 2.84	<0.05
50-59	186.71	274.13	1.47	0.92 - 2.21	N.S.
All Ages	57.6	119.12	2.07	1.12 - 3.58	<0.05

**Haemopoietic/lymphatic
malignancies**

20-29	2.12	17.30	8.16	3.11 - 22.64	<0.01
30-39	3.08	26.43	8.58	3.46 - 19.58	<0.01
40-49	8.32	73.25	8.80	4.13 - 15.27	<0.01
50-59	24.13	108.62	4.47	2.56 - 6.81	<0.01
All ages	6.83	43.12	6.31	3.12 - 14.13	<0.001

The Risk Ratio decreases with increasing age as the unexposed cancer rate increases due to normal aging processes. The Haemopoietic/lymphatic cancers are all highly significantly increased in every age group.

12.1.8 Polish Military Preliminary Prospective Study Results:

Szmigielski (1998) is a prospective study on exposed Polish Military personnel between 1986 and 1990. He concludes that the data suggests that cancers “develop faster, with a shorter latency period” in servicemen with occupational RF/MW exposures. He also found a dose-response relationship with cancer rate against maximum microwave exposure. Individual exposure monitoring places 92.8% of the exposed men in situations where peak exposures were less than $1000\mu\text{W}/\text{cm}^2$, and 83.7 % below $600\mu\text{W}/\text{cm}^2$. This data also includes the all cancer risk ratio for these groups of people.

Table 18: Cancer rates as a function of typical peak exposures in a prospective study extending the Polish Military study, Szmigielski (1998).

Number of Men		Peak Exposure Range $\mu\text{W}/\text{cm}^2$	Cancer Rate Ratio
1900	(49.4%)	100-200	1.69
1320	(34.3%)	200-600	1.57
350	(9.1%)	600-1000	4.62
280	(7.2%)	>1000	4.93

12.1.9 Simplified peak and mean exposure regime:

Based on the Polish Military study measurements the following simplified exposure regime has been proposed. The simplified regime could consist of life-time means being half of annual means while working, annual mean is 20% of the weekly working mean, the weekly peak is 10 times the weekly mean and the monthly peak is 10 times the weekly peak. For example:

Table 19: Estimated life-time, annual, weekly mean and weekly and monthly peak exposure relationships.

Exposure Category	Exposure ($\mu\text{W}/\text{cm}^2$)				
	Life-time Mean	Annual Mean	Weekly Mean	Weekly Peak	Monthly Peak
High	10	20	100	1,000	10,000
Medium	5	10	50	500	5,000
Low	2	4	20	200	2,000

12.1.10 Conclusions:

The three published papers in the Polish Military cancer morbidity study shows that RF/MW is associate with cancer in every major organ of the body, with the highest risks occurring for Leukaemia and Lymphoma. A dose response relationship has been found for the latest study which is a prospective study following a large number of exposed servicemen and monitoring their peak exposures associated with their military work.

The significance of these studies cannot be dismissed because of exposure uncertainties. There is a very good separation of exposed and low exposure populations through one of the world's most advanced personnel exposure monitoring systems. These are also one of the largest of any study thus far. Hence the ICNIRP criticism of these studies is completely unfounded.

These studies, when taken together with the other studies presented here, show a causal relationship between exposure to RF/MW and sickness and death due to cancer increases and very low, mean life-mean exposure levels. All peak exposures are non-thermal (Szmigielski pers. comm.).

13. Residential Studies:

13.1 Introduction

We have already seen that the residential study in San Francisco showed-dose response related childhood cancer death, brain tumor and leukaemia for residential exposure to low intensity microwaves from a TV/FM tower on Mt Sutra. Szmigielski shows that the highest effect of RF/MW exposure of military personnel is Leukaemia and Lymphoma.

ICNIRP cites two residential studies contained in three papers, Hocking et al. (1996) and Dolk et al. (1997a. and b.). They are described by ICNIRP as “have suggested a local increase in leukaemia incidence”, “but the results are inconclusive.”

ICNIRP consistently uses very simple statements to dismiss any adverse effects. Every time a careful consideration of principles, methods, application of epidemiological approaches and consideration of the actual data and exposure regimes, produces a significantly different conclusion. And when sets of studies are considered together, very strong conclusions are drawn. These studies are no exception.

13.2 Hocking, Gordon, Grain and Hatfield (1996): “Cancer incidence and mortality and proximity to TV towers.”

13.2.1 The Study Context:

This study was carried out to allay public fears about siting cell sites in residential properties in Australia, Hocking (pers. Comm.). The authors correctly recognized that mobile phone base stations (cell sites) have not been exposing people long enough to produce cancer because of the cancer latency periods are long. Because of the then dominance of analogue cell phones using FM radiation they decided to study the residents exposed to FM signals from FM radio and TV stations around three tall towers in North Sydney. When the study was commenced Dr Hocking was the Medical Director of the Telstra Research Laboratory. At the time of publication Dr Hocking had become an independent public health consultant and the paper was published with the support of his professional colleagues.

13.2.2 The population Sample:

The cancer data covered 9 municipalities in the north side of Sydney Harbour for the period 1972 to 1990. The exposed population was chosen to be the three municipalities that surrounded three large TV towers, Lane Cove, Willoughby and North Sydney. This gives an "exposed" population of 135,000. The control group came from six surrounding municipalities, Ryde, Ku-ring-gai, Warringah, Manly, Mosman and Hunters Hill, population 450,000, Figure 27.

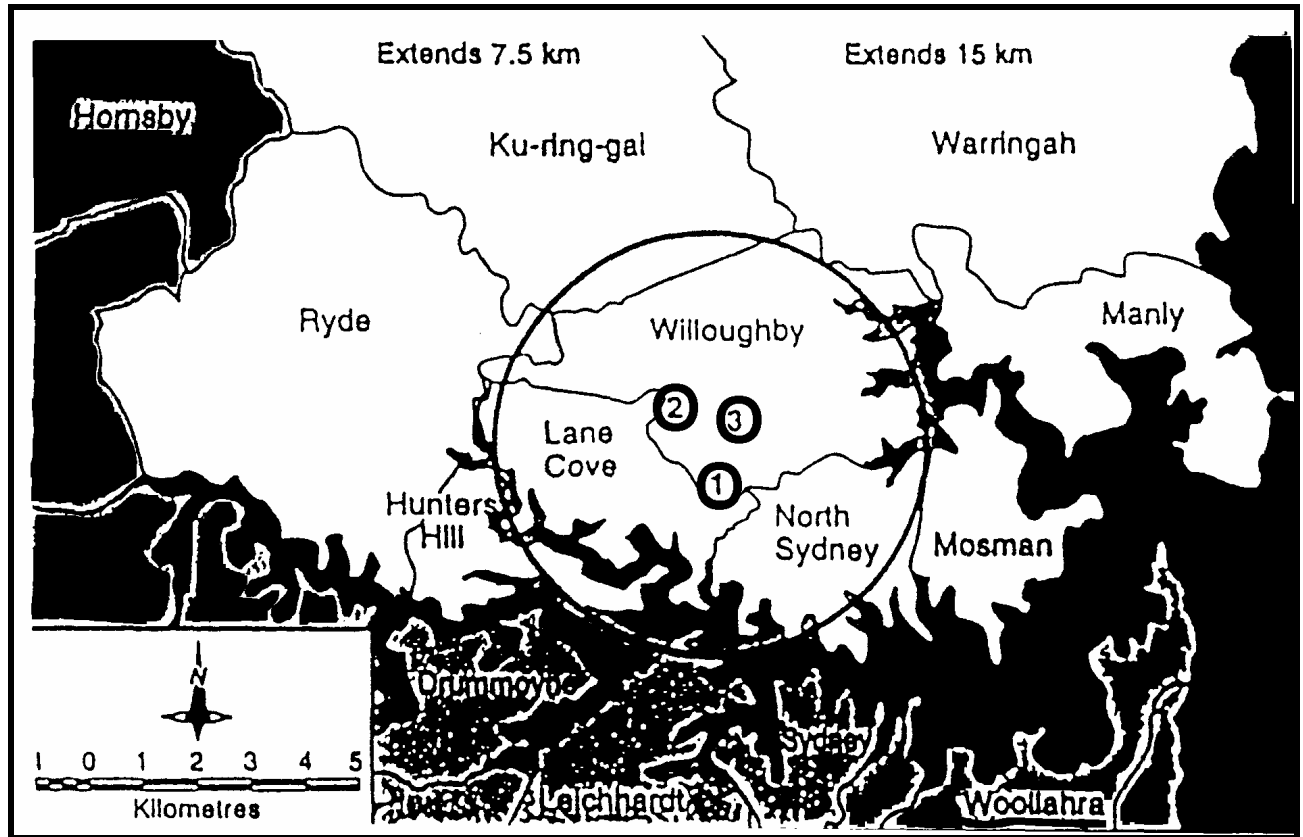

Figure 27: Municipalities in northern Sydney and the TV towers (numbered 1, 2 and 3). The circle has a 4 km radius and is for reference only. Willoughby, Lane Cove and North Sydney are the inner "exposed" municipalities, Hocking et al. (1996).

The cancer incidence (mortality) cases were adjusted for sex, age and calendar period and resulted in 1206 (847) leukaemia cases for the total population and 134 (59) for children 0-14 years. For brain tumour the sample was 740 (606) for the total population and 64 (30) for children.

13.2.3 Exposure situation:

Tower 1 has the highest TV/FM output power, 500 kW, while Tower 2 has 180 kW and Tower 3 110 kW. This shows that the Lane Cove population should experience the highest mean exposure and North Sydney the second highest. The frequencies involved are in the range 63 - 219 MHz and 626-633 MHz. Towers 1 and 2 were increased to these high powers in 1980 with the addition of 340 kW to Tower 1 and 70 kW to Tower 2. In terms of cancer, this is likely to influence the childhood leukaemia and brain tumor

rates more than the adult rates because of longer adult cancer latencies and their age structure.

Two exposure estimates were made. Using the output power of the 4 TV transmitters the combined radial exposure was calculated relative to the centre point of the three towers, neglecting ground reflections. At the center between the towers this gave $1\mu\text{W}/\text{cm}^2$. The highest calculated exposures were between 4 to 8 $\mu\text{W}/\text{cm}^2$ in a narrow ring at about 1 km. These are the areas immediately adjacent to each of the towers where few people reside. Outside this the calculated exposure declines as an inverse square to be $0.2\mu\text{W}/\text{cm}^2$ at 4 km, the limit of the "exposed" population.

The second data set was a number of actual readings taken by the Commonwealth Dept of Communications. These were generally about $1/5^{\text{th}}$ of the calculated values at any point. This is largely explained by sheltering effects of the line-of-site signals, by hills and buildings. It must also be remembered that the population spends a proportion of its time inside, typically at least 10-12 hours, during which the RF exposure will be significantly reduced. A factor of 2 is conservative and is still likely to over estimate the mean population exposures. The results of the calculated and measured exposures are given in Figure 27a.

Figure 27a: Logarithm of the calculated power densities (in $\mu\text{W}/\text{cm}^2$) for TV signals from the three TV towers against distance from the centre of the towers.

The lower limit at the 4 km circle, enclosing the "exposed" population, the estimated mean residential exposure (50% of measured) is $0.025\mu\text{W}/\text{cm}^2$ or $25\text{ nW}/\text{cm}^2$.

12.3.4 North Sydney Study Results:

Hocking et al. shows statistically significantly increased incidence and mortality for total leukaemia, Lymphatic Leukaemia and Other Leukaemia for the whole population, with Risk Ratios in the range 1.09 to 1.67 for leukaemia incidence and 1.01 to 1.57 for leukaemia mortality. The highest relationship is for Lymphatic Leukaemia mortality, $\text{RR} = 1.39$ (95% CI: 1.00-1.92), Table 20.

Table 20: Rate Ratios (RR) and 95% confidence intervals (CI) for cancer incidence and mortality in the population of the inner area compared to the outer area, adjusted for age, sex and calendar period.

Cancer Type	RR (95% CI)	Cases
Incidence		
Brain Tumour	0.89 (0.71-1.11)	740
Total Leukaemia	1.24 (1.09-1.40)	1206
Lymphatic Leukaemia	1.32 (1.09-1.59)	536
Myeloid Leukaemia	1.09 (0.91-1.32)	563
Other Leukaemia	1.67 (1.12-2.49)	107
Mortality		
Brain Tumour	0.82 (0.63-1.07)	606
Total Leukaemia	1.17 (0.96-1.43)	847
Lymphatic Leukaemia	1.39 (1.00-1.92)	267
Myeloid Leukaemia	1.01 (0.82-1.24)	493
Other Leukaemia	1.57 (1.01-2.46)	87

For childhood leukaemia the relationships are generally stronger even though the sample size is smaller. Significant relationships exist for Total Leukaemia and Lymphatic leukaemia incidence and mortality. The strongest relationship is for childhood lymphatic leukaemia death, RR=2.74 (95%CI: 1.42-5.27). the study found that 59 children had died from having leukaemia when the expected number was 25.43, an excess of 33.6 deaths. For childhood lymphatic leukaemia 39 children died when 14.2 were expected, an excess of nearly 25 children, Table 21.

Table 21: Rate Ratios (RR) and 95% confidence intervals (CI) for cancer incidence and mortality in childhood (0-14 years) in the population of the inner area compared to the outer area, adjusted for age, sex and calendar period.

Cancer Type	RR (95% CI)	Cases
Incidence		
Brain Tumour	1.01 (0.59-2.06)	64
Total Leukaemia	1.58 (1.07-2.34)	134
Lymphatic Leukaemia	1.55 (1.00-2.41)	107
Myeloid Leukaemia	1.73 (0.62-14.81)	9
Other Leukaemia	1.65 (0.33-8.19)	8
Mortality		
Brain Tumour	0.73 (0.26-2.10)	30
Total Leukaemia	2.32 (1.35-4.01)	59
Lymphatic Leukaemia	2.74 (1.42-5.27)	39
Myeloid Leukaemia	1.77 (0.47-6.69)	11
Other Leukaemia	1.45 (0.30-6.99)	9

The authors search diligently for confounding factors, including social economic factors, air pollution (benzene), ionizing radiation, migration, hospitals, high voltage power lines and local industries. None affected the relationships found. They investigated the possibility of clustering and found that no significant heterogeneity was found ($p=0.10$ for incidence and $p=0.13$ for mortality).

13.2.4 North Sydney Study Critique:

McKenzie, Yin and Morrell (1998) produced a very useful critique of Hocking et al. (1996). They carried out an analysis cancer rates of more of the municipalities in the Sydney metropolitan area. They also showed that socio-economic status is a risk factor for acute lymphoblastic leukaemia (ALL) in N.S.W. The concentrated of ALL because this was found by Hocking et al. to be the most elevated childhood cancer in the vicinity of the North Sydney TV towers. McKenzie et al. also undertook a number of exposure calculations in an attempt to characterize the mean exposure for each of municipalities.

Their calculations used a simple formula which does not produce side lobes, which for elevated UHF signals do produce and they influence ground level exposures out to beyond 4 km. They highlighted the role of shadowing as a source of lower measured values compared with calculated values. They showed with measurements at a particular location how the exposure varies from direct exposure on the roof ($3\mu\text{W}/\text{cm}^2$), in the garden on the street ($0.066\mu\text{W}/\text{cm}^2$) and inside the home ($0.017\mu\text{W}/\text{cm}^2$). This verifies the factors used for the mean exposure estimates made in section 13.2.3.

Using these 'representative' calculated exposures for each municipality, McKenzie et al. plotted the total childhood cancer incidence rate as a function of the calculated exposure, Figure 27b.

Figure 27b: A dose-response relationship for total childhood cancer in Sydney, Australia, from McKenzie, Yin and Morrell (1998), with the 95% confidence intervals added. RFR exposure is the calculated exposure at the geographic centroid of each municipality.

Hocking et al. (Hocking, Gordon and Hatfield (1999)) reject the substance of the criticisms of McKenzie, Yin and Morrell, concluding:

"In summary, we consider that the second look at our study had important deficiencies regarding post hoc analysis of data. Their conclusion that their analysis 'casts doubt on the apparent association between childhood incidence of acute lymphoblastic leukaemia and television RFR' is not justified. If anything, their analysis confirms our own finding of a modest association, which warrants further study."

In this report the contention is that the conclusion is even stronger than seen by Hocking et al. The calculated exposure used by McKenzie et al. does not take into account the very much higher power being radiated from Tower 1. When this is noted, Lane Cove has the highest calculated mean exposure, North Sydney is next closely followed by Willoughby. If in Figure 27b, Willoughby was moved to $0.5\mu\text{W}/\text{cm}^2$ then the results form an even stronger dose-response relationship than is shown by their original assumptions. The error of not taking into account the radiative power of each tower is significant.

The North Sydney Study shows significant increases in adult and childhood leukaemia incidence and death. When realistic estimates of the mean exposure of each municipality is used, a dose-response relationship results. Measurements confirm that the estimates of the mean population exposure at the 4 km ring, the outer edge of the 'exposed population', is about to $25\text{ nW}/\text{cm}^2$.

13.3 United Kingdom Regional TV Tower Study:

Dolk, Shaddick, Walls, Grundy, Thakrar, Kleinschmidt and Elliott (1997): "Cancer Incidence near Radio and Television Transmitters in Great Britain: 1. Sutton Coldfield Transmitter".

Dolk, Elliott, Shaddick, Walls, and Thakrar (1997): "Cancer Incidence near Radio and Television Transmitters in Great Britain: 2. All High Power Transmitters."

13.3.1 The Study Context:

Dr Helen Dolk and her colleagues responded to concerns about a cluster of seven cases of leukaemia and lymphoma who were patients of a Birmingham GP, Dr Mark Payne, and who lived near the Sutton Coldfield Transmitter. They obtained data from the cancer registry and found a high incidence of adult leukaemia near the tower, which declined with distance. They assumed that this was a dose-response relationship which was following an inverse square law for exposure decline with distance from the transmitter. Before they published this result they decided to extend the study to 20 other regional TV towers throughout the United Kingdom. At these individual sites, and for all the 20 sites combined, the adult leukaemia rate was found to be low near the tower, rose to form a broad variable peak between about 1 km and 5 km, and then declined with distance. It didn't follow an inverse square law and therefore failed to confirm the result found at Sutton Coldfield. This Dolk et al. (1997b) concludes that the follow-up study "at most gives very weak support to the Sutton Coldfield findings."

ICNIRP accepts this conclusion and states that the results of these U.K. studies "are inconclusive".

It has already been shown that VHF and UHF broadcast tower transmissions follow a complex radial pattern. For UHF transmissions the ground level exposure, Figure 14, is low near the tower, rises to a broad variable peak between 1 and 5 km and then declines with distance out to 10 km (the limit of the Dolk et al. studies). When VHF signals are involved, Figure 13, some side-lobe peaks occur within 1km radius of the base of the tower.

This immediately changes the approach to the U.K. study results.

13.3.2 U.K. Cancer Study Results:

A range of body cancer sites were analysed as a function of radial distance from the Sutton Coldfield transmission Tower, Dolk et al. (1997a). The data was obtained and analysed by the Small Area Health Statistics Unit of the Department of Epidemiology and Public Health of the Imperial College of Medicine, London. They obtained adult (≥ 15 years) cancer data for a wide range of cancers, but childhood (0-14) data was limited to all cancer and all leukaemia. The period was 1974-1986. The population living within 10 km of the Sutton Coldfield transmitter was 408,000 from the 1981 census. For the complete data set there was a statistically significant 3 % increase in all cancer with 10 km radius of the transmitter compared to regional expected rates (O/E = 1.03, 95%CI: 1.02-1.05).

13.3.3 Cancer results:

This study involves a far smaller sample than the San Francisco study, less than half a million compared to several million total population, but this study considers a wide range of cancer types for adults as well as for children. However, the population of children involved is very small, especially in the "exposed" group, and therefore reaching statistical significance is unlikely. For example, at Sutton Coldfield there are 97 children with cancer within 10 km of the tower. Within 2 km of the tower there were two childhood leukaemia cases when 1.1 was expected. This gives RR = 1.82 but is far from significant. Hence the Sutton Coldfield study cannot reliably address the childhood cancer issue. This problem, of small numbers, also limits the reliability of relationships with individual cancer types, especially close to the towers where population numbers are necessarily small.

For adult cancers the results are presented in the following two tables.

Distance from transmitter (km)	All cancers*				All leukemias				Non-Hodgkin's lymphomas

Figure 28a: Radial adult cancer rates around the Sutton Coldfield TV transmission tower.

These tables show two radial cancer patterns:

- For All Cancer, Non-Hodgkin's Lymphoma, Skin Melanoma and Bladder cancer the cancer rates are low near the tower, rise to a complex broad peak between 1 km and 10 km. The skin melanoma drops faster than all the others. This is typical of UHF radiation patterns, Figure 28.
- Adult leukaemia has 6 people within 1 km. This gives a high O/E ratio close to the tower. In all other respects it is similar to the first group. This is typical of mixed VHF/UHF radiation patterns, Figure 28a.

Figure 28b shows how the ground level radial radiation exposure pattern follows systematic periodic functions which are a dependent on the frequency. UHF signals include even higher frequencies whose main beam peaks occur even further away from the tower than the 300 MHz signal in this figure, Pattern A. The VHF signals follow Pattern B. Pattern A for radial cancer rates also occurs when few people live near the tower, resulting in low cancer rates inside 2km. Dolk et al. recognize the complexities of the radial RF-radiation pattern with the statement: Dolk et al. (1997a)

“Field strength measurements have been made in the vicinity of the transmitter (British Broadcasting Corporation, BBC). In general both measured and predicted field strength values tended to show a decline in average field strength or power with distance from the transmitter, although there are undulations in the predicted field strength up to distances of about 6 km from the transmitter resulting from the vertical radiation pattern. The maximum total power density equivalent summed across frequencies at any one measurement point (at 2.5m above ground) was 0.013 W/m^2 ($1.3 \mu\text{W/cm}^2$) for TV, and 0.057 W/m^2 ($5.7 \mu\text{W/cm}^2$) for FM. However, there was considerable variability between different measurement points at any one distance from the transmitter, as one would expect from the impact of reflections from ground and buildings, and this variability was as great as that related to distance. Power density on average declines by a factor of 5 to 10 over 10 km.”

Figure 28b: Typical antenna and health effect patterns around broadcast transmission towers. Pattern A (dashed) is typical of UHF antennae and health effects patterns with no VHF and/or low population numbers near the tower.

However, this understanding, and the understanding of the importance of frequency, did not appropriately inform their conclusions.

TABLE 2. Cancer Incidence near 20 high power radio and TV transmitters in Great Britain—all leukemias: observed (O) and expected (E) numbers of cases, O/E ratios, and cumulative O/E ratios, for all transmitters combined, for transmitter groups, and selected individual transmitters, by distance of residence from transmitter, in persons aged ≥ 15 years, 1974–1986

Figure 30: Cancer data for the 20 site U.K. study from Dolk et al. (1997b).

Figure 30 shows in the course radial analysis that Skin Melanoma is higher close to the towers whereas Bladder Cancer is more broadly elevated, consistent with Sutton Coldfield.

13.3.4 Site Difference Analysis:

Thus we find a great deal of consistency between the Sutton Coldfield data and the 20-site data. There is only one major exception, the high rate of adult leukaemia near the Sutton Coldfield Tower.

For a cancer rate to be detected as high near an RF transmission tower three factors must occur, Cherry (2001):

1. There must be a large population. This requires a high population density because there is only a small area within 1 km radius of the tower and a high proportion of this is likely to be the open field in which the tower itself is sited.
2. There needs to be a high radiation exposure for the radiation to be able to elevate the cancer rate. This occurs for the lower frequency, VHF, FM signals, Figure 13.
3. The cancer type needs to be RF-radiation sensitive to assist in raising the cancer incidence above the background level. Leukaemia and Lymphoma are very RF-sensitive cancers, Szmigielski (1996), Milham (1985, 1988), Hocking et al. (1996).

There are only two high powered sites in high population areas in the study, Sutton Coldfield near Birmingham and Crystal Palace in London. Dolk et al. (1997b) notes that of the Sutton Coldfield tower has VHF FM but Crystal Place does not. Thus the three factors set out above are only met at Sutton Coldfield. This is sufficient to explain the only significant difference between these data sets. Hence for all cancers in Dolk et al. (1997a and b), taking into account the radiation exposure differences, all the data is consistent.

Figure 31: Other cancer sites in the broad radial analysis from Dolk et al. (1997b).

The studies of Dolk et al. show that residential cancer rates vary as the RF radiation patterns vary and hence the wide range of cancers, including Leukaemia, Non-Hodgkin's Lymphoma, Bladder cancer and Skin Melanoma. Figure 31 shows that a number of other cancers are elevated closer to the tower but no detailed radial patterns are given for them. They include Male and Female Breast Cancer and Prostate Cancer.

13.3.5 Childhood Cancers:

The ability of these studies to detect childhood cancers was severely limited by small number of children who live within 10 km of these TV Transmission Towers. While in the 21 sites there were 3609 adults (≥ 15 years) with leukaemia, there were only 317 children (≤ 14 years). Close to the towers, i.e. inside 2 km there were 101 adults and 10 children with leukaemia. The expected incidence was 94.17 and 8.94 respectively. This gives O/E = 1.073, 95%CI: 0.81–1.42 for adults and O/E = 1.12, 95%CI: 0.61–2.06 for children.

This the childhood leukaemia rate is elevated around the 21 TV transmission towers in the United Kingdom, more so than the adult rate, but the small numbers mean the elevation is not significant.

For brain tumours, the rate is elevated within 10 km of the towers, for Malignant and Benign Brain Tumour O/E = 1.06, 95%CI: 0.93–1.20, $n=224$, and for Malignant Brain Tumours, O/E = 1.03, 95%CI: 0.90–1.18. It would have been interesting to observe the radial cancer rates for these tumours for the numbers involved are much higher than for the Sutra Tower Study. The equivalent data from the North Sydney Study is for Childhood Leukaemia O/E = 1.8, 95%CI: 1.2–2.5, $n=33$ and for Brain Tumour O/E = 1.3, 95%CI: 0.7–2.3, $n=12$. Hocking et al. use a 4 km radius whereas the UK data is for a 10 km radius. There is a different mix of TV and FM signals and signal strengths in the North Sydney Study than in the UK Study. Accepting these differences they all show elevated leukaemia and brain tumor. The very large output power of the Sutra Tower results in far higher childhood cancer rates.

13.3.6 Exposure Assessment:

Excesses in cancer are still seen at 10 km, where the direct exposure is 5 to 10 times less than the UHF peak of $1.3\mu\text{W}/\text{cm}^2$, i.e. between 0.13 and $0.26\mu\text{W}/\text{cm}^2$. Applying the lifetime mean factor of 0.15 for residential exposure reduces the exposure associated with these adverse health effects to the range 0.02 to $0.034\mu\text{W}/\text{cm}^2$.

This is consistent with the widely identified no observable adverse effect level of $0.02\mu\text{W}/\text{cm}^2$.

13.3.7 Conclusions about the UK TV Tower Study:

If the authors had known about and applied the available engineering knowledge they would have concluded that there was a significant dose-response relationship between a number of adult cancers and RF exposure from TV/FM transmission towers. There is complete internal consistency once the different radiation patterns are recognized. The study also shows elevations in cancers from sites all over the body, with dose-response relationships being evident for those presented. Hence the observations are consistent with the data in Selvin et al.(1992) data and analysis of Szmigielski (1996).

The data in Dolk et al. is internally consistent, shows elevated childhood leukaemia and brain tumor, and a set of dose-response relationships which are likely to be highly significant, if related to realistic radial RF patterns, for cancer at a wide range of body sites including All Cancer, Leukaemia, Non-Hodgkin's Lymphoma, Brain Cancer, Bladder Cancer, Prostate Cancer, Skin Melanoma, Male and Female Breast Cancer and Colorectal Cancer. This is also consistent with Robinette et al. (1980), Szmigielski (1996) and Milham (1985, 1988).

14. Additional studies not cited by ICNIRP:

There is a large body of epidemiologic scientific literature that is relevant to the assessment of RF/MW exposures risk of cancer. Almost all of these studies have not been referenced in the WHO/UNEP/IRPA review, WHO (1993), that is cited by ICNIRP to be one of the "more detailed reviews". In fact the ICNIRP review covers more published studies than does the WHO/UNEP/IRPA review, but both ignore most of the published epidemiological studies. Three of the studies cited by WHO (1993) are omitted by ICNIRP. They are the case study by Archimbaud et al (1989), and Air Force Base studies of Lester and Moore (1982) and Lester (1985) and Amateur Radio Study of Milham (1985). WHO (1993) omits the Wichita Kansas Study of Lester and Moore (1982a) and the Operator Electrical Workers Study of Milham (1985) and the Amateur Radio Operators study, Milham (1988).

WHO (1993) and ICNIRP(1998) share many of the flawed methodological approaches and the assumption of the RF-thermal effect that the only RF/MW effect is heating of human tissues. The review teams were chaired by the same person during most of the 1990's, Dr Michael Repacholi.

WHO (1993) states that no significant effects were found in Lilienfeld et al. (1978). This has been proved here to be wrong. The U.S. Air Force Bases Studies are described as "contradictory" because Polson and Merritt (1985) correctly criticize Lester and Moore for relating cancer rates in counties to the existence of Air Force bases in those counties when many cities which are close to Air Force bases are in adjacent counties without Air Force bases. Lester (1985) adjusted the analysis accordingly and concludes:

"This strengthens the possibility of an association between some factor associated with AFBs - our original hypothesis was microwave radiation - and cancer incidence because we now explicitly recognize the use of the county containing the city nearest the base, which would be expected to be a truer indicator of the effect produced by some factor emanating from the base than would a county in which the base is situated but in which the nearest city is farther away."

WHO (1993) ignore the significance of the correction, which is in the same issue of the journal as the Polson and Merritt paper, revealing the bias towards dismissing evidence of effects.

WHO (1993) acknowledges that Szmigielski et al. (1988) and Archimbaud et al. (1989) show a relationship between RF/MW and increased risk of cancer, including Acute Myelogenous Leukaemia. In the case of Milham (1985) the increase in Leukaemia is acknowledged. However, the result is questioned because it is noted that many of the Amateur radio operators are also employed in the "Electrical Industries". Hence they are exposed to PCBs, solvents, fumes, and 50/60 Hz magnetic fields and not 300Hz-300GHz radiation. This claim is challenged by evidence which supports the EMR Spectrum Principle because many ELF drive appliances also emit RF/MW radiation which is much more electrobiological active.

The overall WHO (1993) conclusions include the statements:

"In summary, the epidemiological and comparative clinical studies do not provide clear evidence of detrimental health effects in humans from exposure to RF fields". And

"The question of whether RF might act as a carcinogen should be further evaluated in epidemiological studies."

This question could have been somewhat resolved if the studies cited had been more appropriately interpreted and if the associated studies that were omitted had been included.

Lester and Moore (1982a) is their initial study which tested the hypothesis that radar might increase the risk of cancer by noting that Wichita Kansas had radar sets on Air Force Bases on two opposite sides of Wichita. The tested the hypothesis by separating populations which were exposed to no radar signals, living in valleys, one radar signal, on one or other hill slope, and two radar signals by living on ridges. The cancer incidences are 303, 429 and 470 per 100,000 (1.00:1.42:1.55). The dose-response association persisted through age, sex, race and socio-economic adjustments.

Dr Sam Milham's two other studies not cited in WHO (1993) are Milham (1985a), a large study of Electrical Workers in Washington, and Milham (1988) and updated Amateur Radio Study covering California and Washington.

Milham (1988) studied 67,829 amateur radio operators in Washington State and California. He concludes "The all-cause standardized mortality ratio (SMR) was 71 but a statistically significant increased mortality was seen for cancers of the other lymphatic tissues (SMR = 162), a rubric which includes multiple myeloma and non-Hodgkin's lymphomas. The all leukemia SMR was slightly elevated but not significant (SMR = 124). However, mortality from acute myeloid leukemia was significantly elevated (SMR = 176). Elevated cancer rates were found for Esophagus, SMR = 113 (71-172); Large Intestine, SMR = 111 (89-137); Prostate, SMR = 114 (90-142); Brain, SMR = 139 (93-200), Lymphoma + Leukaemia, SMR = 123 (99-152); Hodgkin's Disease, SMR = 123 (40-288); Leukaemia, SMR = 124 (87-172) and Other Lymphatic Tissue, SMR = 162 (117-218).

Milham (1985a) studied cancer rates in 486,000 adult male workers who were in occupations in Washington State which had potential exposures to electromagnetic fields. This showed elevated and significantly elevated cancer rates in many body organs. The results are summarized in Table 22.

Table 22: Summary of all site cancers from Robinette et al. (1980), using AT/ET except for Brain cancer (FT/ET), Milham (1985a), Szmigielski (1996) and for Dolk (1997a,b) using the maximum and/or significant result in the radial patterns.

Exposure Regime	Robinette RF/MW High	Milham Mixed Mod.	Szmigielski RF/MW High	Dolk(a) RF/MW Low	Dolk(b) RF/MW Low
Relationship	RR	PMR	RR	O/E	O/E
Sample Size(N)	202	2649	55,500	17409	13372
Symptoms					
All Malignant Neoplasms	1.66*	106**	2.07*	1.20*	
Esophageal and Stomach			3.24**		
Respiratory Tract, Lung	1.75	114**	1.06		
Colorectal/ bladder (1)			3.19**	1.36/1.76	1.10
Liver, pancreas		117*	1.47		
Skin, Melanoma	2.66		1.67*	2.39*	1.11
Thyroid			1.54		
Brain, CNS (2)	2.39	143**	1.91*	1.31	1.06

Acute Leukaemia (Lympho)		162**	5.75*	3.57	1.04
Acute Myeloblastic Leuk.			8.62***	1.02	1.17
Chronic Myelocytic Leuk.			13.90***	1.23	
Chronic Lymphoblastic Leuk			3.68**	2.56*	1.20

p-values: * <0.05; ** <0.01; *** <0.001

Note (1): Colorectal for Szmigielski and the left Dolk(a) and bladder for the right Dolk(a) and Dolk(b).

Note (2): In Milham 16 of the unspecified neoplasms were brain tumors which have been added to this group.

Table 22 shows a great deal of consistency between several large studies which stand as proof, backed by many dose-response relationships, even at residential exposure levels, that RF/MW increases the risk of cancer over the whole body. This stands in strong contrast with the ICNIRP and WHO review conclusions.

The following is a brief summary of a number of relevant epidemiological studies which have been omitted by both WHO (1993) and ICNIRP (1998).

Table 23: Brief Summary of a sample of epidemiological studies, especially those involving cancer in EMR exposure situations.

It is not widely recognized that ELF epidemiological studies have relevance to RF/MW assessments of effects. There are two primary reasons for this. High voltage power lines are sources of RF radiation, especially in the 3 to 30 MHz range. This is why you often hear a buzz on your radio as you drive under a powerline. This is outlined as part of the EMR Spectrum Principle. This evidence proves that epidemiological studies of RF/MW and ELF show elevated and significantly increased cancer in many body organs, but especially brain cancer, leukaemia and breast cancer.

- More neurasthenic symptoms (chronic mental and physical weakness and fatigue) in group exposed to radar (Djordjevic et al., 1979).
- Higher frequency of increase in red blood cells (polycythemia) with microwave exposure (Friedman, 1981).
- Lin et al. (1985) studied 951 cases of brain tumors among white male residents of Maryland during the period 1969-1982. Fifty cases of glioma and astrocytoma were observed among electrical workers exposed to EMR compared to an expected number of 18, i.e. an risk ratio of 2.8. While their exposure was mainly to ELF fields it shows the common link over a wide range of frequencies. A significant dose-response relationship was found: No exposure: 1.00; Possible exposure OR = 1.44(1.06-1.95); Probable exposure, OR = 1.95 (0.94-3.91), and Definite exposure, OR = 2.15 (1.10-4.06).
- In 1985 an unusual number of children with leukaemia were identified living in the vicinity of broadcasting facilities (OR = 3.4: CI=0.70 -16.41), Maskarinec et al. (1993).
- Upper limb paraesthesia and eye irritation among 30 exposed workers using 27 MHz plastic sealers (Bini et al., 1986);
- De Guire et al. (1987) report increased malignant melanoma of the skin in workers in a telecommunication industry, affecting only men, SIR = 2.7 CI : 1.31-5.02).
- Thomas et al. (1987) report a 10-fold increase in astrocytic brain tumor among electronics and repair workers employed for 20 years or more. Some risk was due to solvents, put at a factor of 2, placing RF/MW contribution at a factor of 5.

- Electrical workers in Los Angeles county have a 4.3-fold increased risk of certain brain tumors (Preston-Martin et al. 1989).
- An increased incidence of malignant brain tumors has been reported in children of fathers exposed to electromagnetic fields and electronic solvents (Johnson and Spitz, 1989).
- Increased protein band in CSF in exposed group of radar mechanics (Nilsson et al., 1989).
- Hayes et al.(1990) report an Odds ratio for all testicular cancer of 3.1 (CI: 1.4-6.9) for a small sample of workers who were occupationally exposed to RF/MW radiation.
- Navy Electrician's Mates have an excess risk of leukaemia, RR=2.4 (1.0-5.0), Garland et al. (1990)
- Savitz and Chen (1990) show significant increased risk of childhood cancer (Neuroblastoma (OR=11.8*), Brain Tumour (OR=2.7*) and CNS tumors (OR=1.7)) associated with parents who work in electrical and electronic industries.
- Increased risk for all brain tumours (RR=2.9 (1.2-5.9)) and glioblastomas (RR=3.4 (1.1-8.0)) for assemblers, and repairmen in the radio and TV industry, Tornqvist et al. (1991)
- Microwave heating reduces immune system factors in human breast milk, compared to conventional heating. Microwave heating significantly reduces the IgA for E coli bacteria, producing five times more E coli for 25 °C heating and 18 times more after 3 hours for 98°C heating, Quan et al. (1992).
- Floderus, Tornqvist and Stenlund (1994) found a significant increase in Brain Tumours, RR = 12.2, 95%CI:2.8-52.5; Breast Cancer, RR = 4.9, 95%CI:1.6-11.8 and pituitary tumours, RR = 3.2, 95%CI:1.6-6.2, for electrical railway workers younger than 30 yrs.
- Loomis, Savitz and Ananth (1994) found significant increases in Female Breast Cancer in Electrical Workers, OR = 1.38 (95%CI: 1.04-1.82). Adjusted ORs for electrical engineers, OR = 1.73 (95%CI: 0.92-3.75); for electrical technicians, OR = 1.28 (95%CI:0.79-2.07) and for telephone installers, repairers and line workers, OR = 2.17 (95%CI:1.17-4.02).
- Women working in the Telephone Industry showed many excess cancers. Among white women (age <49) Rectum Cancer MOR = 3.3 (1.2-8.7); connective tissue MOR = 4.4 (2.2-8.2); Breast Cancer MOR = 1.6 (1.2-2.1), corpus uteri MOR = 3.3 (1.5-7.5, Ovary MOR = 2.1 (1.3-2.5); and Brain MOR = 2.1 (1.2-3.7). Excess risks of connective tissue cancer among engineers and technicians; office workers; telephone operators; and mechanics and repairers, MOR = 8.5, 4.9, 1.7, and 4.4 respectively, Dosemeci and Blair (1994).

- Significantly increased and dose-response increases of total Mortality, All Cancer, Leukaemia and Brain Tumour were found in US Utility Workers (1950-1988) and subset of occupations, Savitz and Loomis (1995).
- Increased risk of female breast cancer with exposure to radiofrequency EMF, RR=1.15 (1.1-1.2), Cantor et al. (1995).
- Tynes et al. (1996) observed an excess risk of Female Breast Cancer for female radio and telegraph operators exposed to RF (405 kHz-25 MHz), SIR = 1.5 for > 50 yr of age.
- The Skrunda Radar provides a living laboratory for the chronic low level effects of exposure to RF/MW radiation. To date investigations have revealed a number of statistically significant changes associated with exposure to the radar signal. These include:

Impaired physical and scholastic performance of children in the open field exposure range of 0.0008-0.41 $\mu\text{W}/\text{cm}^2$, mean measured level in the range 0.0028-0.039 $\mu\text{W}/\text{cm}^2$.

A 6-fold increase in broken chromosomes in the peripheral erythrocytes of the exposed cows ($p < 0.01$). for a measured exposure would be in the range 0.042 to 6.6 $\mu\text{W}/\text{cm}^2$, mean exposures in the range 0.157 to 0.63 $\mu\text{W}/\text{cm}^2$.

A statistically significant ($P < 0.01$) negative correlation between the relative additional increment in tree growth and the intensity of the electric field. The Pine trees at 4 km were exposed to a range of 0.011 to 0.41 $\mu\text{W}/\text{cm}^2$, a mean open field exposure of 0.039 $\mu\text{W}/\text{cm}^2$ and measured distance exposure of 0.0027 $\mu\text{W}/\text{cm}^2$ (for the radar signal). A probable biological mechanism was identified through observed changes in physiological conditions.

Chromosome and reproductive damage in plants exposed RF/MW in the range 0.042 to 6.6 $\mu\text{W}/\text{cm}^2$.

Chronic exposure to pulsed RF radar signals is associated with chromosome damage in plants and animals, with associated reproductive aberration in plants, and growth reduction in pine trees linked to observed physiological changes, and scholastic impairment of school children occurs in relation to exposure levels which fall well below 2 $\mu\text{W}/\text{cm}^2$, below 0.1 $\mu\text{W}/\text{cm}^2$. and even below 0.01 $\mu\text{W}/\text{cm}^2$.

- Stenlund and Floderus (1997) identified increased Testicular Cancer in middle ELF exposure ($> 0.28 \mu\text{T}$) and high exposure ($> 0.4 \mu\text{T}$) compared with low exposure ($\leq 0.15 \mu\text{T}$) with OR = 1.3 (CI:0.7-2.5) and OR = 2.1 (CI:1.0-4.3) for those ≤ 60 years and OR = 1.9 (CI:0.8-4.4) and OR = 3.9 (CI:1.4-11.2) for men ≤ 40 years. These produce significant ($p < 0.05$) dose-response relationships.
- Occupational risks of Brain Tumours includes telephone and radio operators, electricians, OR = 1.2 (0.2-5.2) for All Brain Tumour and OR = 1.4 (0.2-8.7) for malignant Brain Tumours, Kaplan et al. (1997)

----- End of Table 23 -----

15. Summary:

These many papers are a small sample of the total available. They confirm the EMR Spectrum Principle that health effects occur across the spectrum from ELF to RF/MW and in mixed exposures. Leukaemia, Brain Tumour and Breast and other hormonal related cancers are most commonly associated with EMR exposure. Compared to chemical assessments, the strength of evidence that there is a cause and effect relationship between EMR and cancer exceeds that of most substances that are classified as human carcinogens.

15.1 Leukaemia Overview:

When the TF/MW studies which have identified significant increases in Adult Leukaemia are ranked from residential, recreational, occupational and military exposures, they form a global dose-response relationship, Table 24.

Table 24: A summary of epidemiological studies involving adult leukaemia mortality or incidence, ranked by probable RF/MW exposure category.					
Study	Reference	Exposure Category	Leukaemia Type	Risk Ratio	95% Confidence Interval
Polish Military (Mortality)	Szmigielski et al., 1996	High	ALL	5.75	1.22-18.16
			CML	13.90	6.72-22.12
			CLL	3.68	1.45-5.18
			AML	8.62	3.54-13.67
			All Leuk.	6.31	3.12-14.32
Korean War (Mortality)	Robinette et a. (1980)	High	All Leuk.	2.22	1.02-4.81
Amateur Radio (Mortality)	Milham (1988)	Moderate	AML	1.79	1.03-2.85
UK TV/FM (Incidence)	Dolk et al. (1997a)	Mod/Low	Adult Leuk.	1.83	1.22-1.74
			CML	1.02	0.28-2.60
			AML	1.86	0.89-3.42
			ALL	3.57	0.74-10.43
			CLL	2.56	1.11-5.05
North Sydney TV/FM towers (Mortality)	Hocking et al. (1996)	Low	All Leuk.	1.17	0.96-1.43
			ALL+CLL	1.39	1.00-1.92
			AML+CML	1.01	0.82-1.24
			Other Leuk	1.57	1.01-2.46
UK TV/FM (Incidence)	Dolk et al. (1997b)	Low	Adult Leuk.	1.03	1.00-1.07
			CML	1.16	
			AML	1.17	
			ALL	1.04	
			CLL	1.20	

Note: ALL : Acute Lymphatic Leukemia; CLL: Chronic Lymphatic Leukaemia; AML Acute Myeloid Leukaemia; CML: Chronic Myeloid Leukaemia; and All Leuk.: All Adult Leukaemias.

Thus the balance of evidence becomes zero no effects studies to 10 studies giving very strong evidence of increased cancer.

The studies cited by ICNIRP contain sufficient evidence to conclude cause and effect between RF/MW and cancer across many body organs, Hill (1965), especially leukaemia and brain tumour, and at chronic lifetime exposures showing dose-response relationships pointing to a Level of No Observed Adverse Effects threshold of about 20nW/cm².

This is confirmed by more than twice as many studies as are cited by ICNIRP (1998), this confirming the cause and effect relationship between RF/MW exposure and cancer.

Support also comes from ELF studies and those involving "Electrical or Utility" Occupations because of the validity of the EMR Spectrum Principle.

15.2 The ICNIRP 1998 assessment

The ICNIRP assessment suffers from the same systematic errors, misrepresentations, selections and wrong interpretations and conclusions as the WHO/UNEP/IRPA 1993 Review and the 1996 ICNIRP statement (Repacholi, 1996).

It appears to follow the balance of probabilities approach but it carefully cites only perceived positive and negative findings to accomplish the negative conclusion. For example ICNIRP (1998) cites only 13 papers, assessing 8 as no effects studies and 5 as showing effects but being so flawed that they cannot be taken as showing serious effects. Thus, on the balance of probabilities (8:5) they conclude:

“Overall, the results from a small number of epidemiological studies published provide only limited information on cancer risk.”

It is so flawed as to be scientifically incredible and worthless, misleading and dangerous for public health protection.

When the studies are investigated in detail and in context it is shown that three of the papers are not appropriately included because they cannot and do not assess the risk of cancer. This leaves 10 papers which relate to 5 studies which ICNIRP claims show no

effects and 3 studies which do show significant effects are described as weak, inconclusive, or have poorly described populations and exposure descriptions. Hence the balance reduces to 5 "no effects" studies to 3 "effects studies".

The 5 studies claimed to show no effects all show significant increases in cancer in association with RF/MW exposure. All but one, Grayson (1996), include dose-response relationships. Two, Grayson and Beall et al. only relate to significant increases in brain and CNS cancer, the later showing a significant dose-response relationship. The remaining three all show increases in brain cancer. Three, Lilienfeld et al, Robinette et al. and Selvin et al. show increases in cancer in many body organs, the later two with significant dose-response relationships. Hence contrary to the ICNIRP claim that these five studies don't show increases in cancer, they all do, with many significant and highly significant increases and many dose-response relationships.

16. Conclusion and Recommendations:

16.1 Brief Overview:

The ICNIRP assessment is grossly biased by selectively choosing studies, consistently misrepresenting the results, the significance of results, the implications of the results of cellular experiments, animal experiments and human studies. The large number of published studies are a consistent and coherent set of evidence, that RF/MW is causally associated with reproductive and cancer effects, as well as altering and impairing brain function, reaction times, sleep and learning, and impairment of the immune system. There is compelling and consistent evidence of cancer, especially leukaemia and brain cancer. The hypothesis that RF/MW radiation is a Ubiquitous Universal Genotoxic Carcinogen, is the best and only available scientifically plausible explanation that integrates and explains all of these results.

The table above summarizes results of studies on RF/MW exposure and adult leukaemia incidence and mortality. It shows the repeated finding of Leukaemia, and various forms of Leukaemia, with a distinct, significant and appropriate gradient of Risk Ratio with the level of group exposure. Thus a causal relationship is supported by dose response relationships within studies, consistency between studies and an ecological dose response relationship with all studies taken together.

Note that childhood leukaemia has also been found to be elevated an extremely low mean intensity and residential situations, Dolk et al. (1997a. and b.) , Maskarinec and Cooper (1993) and significantly elevated, Selvin et al. (1992) reanalyzed, and Hocking et al. (1996). and Michelozzi et al. (2002).

The evidence shows effects relating to genetic cellular alteration, including chromosome aberrations and DNA breakage, which leads to neoplastically transformed cells, which leads to reproductive and cancer effects in animals and people. Together this indicates a causal adverse effect with a level of no observed adverse effects level for cancer and reproductive adverse effects near $0.06\mu\text{W}/\text{cm}^2$.

However brain function alteration, associated with melatonin reduction and induced calcium ion alteration has been observed down to $0.0004\mu\text{W}/\text{cm}^2$ or $0.4\text{ nW}/\text{cm}^2$. Human biometeorology has identified significant brain altering effects at even lower levels of exposure to particular combinations of modulated RF fields, the modulation frequencies

of which appear to relate to EEG frequency bands in the ELF region, but the ELF signal is carried into tissue by RF carriers.

16.2 In the Context of Natural Electromagnetic Radiation:

When all of the results in the context of a global natural electromagnetic radiation signal, the Schumann Resonance signal, Cherry (2002), the results and the hypothesis make very solid sense. Cherry (2002) shows that there is very strong evidence to support the hypothesis that the Schumann Resonance (SR) Signal is detected by the brain, and the SR signal synchronizes the ELF activity of the brain. Adey (1980,1988) shows that brain tissue responds to external ELF modulated signals by altering the rate of flux of calcium ions through neurons, at extremely low induced issue field intensities down to 10^{-8} V/cm. The brain's circadian and ELF activity is synchronized by this signal with a matching frequency range being resonantly absorbed in the brain tissue. Solar and Geomagnetic Activity (S-GMA) induces changes in human health, including cancer, through modulating the SR signal, altering brain activity and altering melatonin production. The SR signal is a mainly tropically sourced radiating ELF signal, that has been chronically globally available. The SR signal has a mean vertical electric field strength in the range 0.22-1.12 mV/m (0.013 - 0.33 pW/cm²), averaging about 0.1 pW/cm². The magnetic field component is typically in the range 1 to 6 pT.

The natural electromagnetic sensitivity of the brain gives a strong basis for accepting that electromagnetic field and radiation exposures at thousands to millions of times higher intensity than the natural SR signal, can damage brain tissue and could cause brain cancer if the damage is genetic. For mobile phones the user's head is exposed to over a billion times higher intensity than the Schumann Resonance signal. A second vital factor for brain damage is the primary need for damaged brain cells to be repaired if possible, because of the nearly total lack of replacement. Melatonin plays a vital role in free radical scavenging and in the competence of the immune system, Reiter and Robinson (1995).

With S-GMA activity, though the Schumann Resonance signal, altering human melatonin, Cherry (2002), then it is shown to be causally associated with a homeostatic relationship with variations in rates of cancer, cardiac, reproductive and neurological diseases and mortality, though a large body of multiple, independent studies. Cherry also shows that similar effects are identified to be significantly and dose-response elevated in people in electrical occupations.

17. Recommended Public Exposure Standard:

There is very strong evidence, from multiple, independent studies, many with dose-response relationships, and many with isothermal or non-thermal or very low exposure levels in some studies, that radio frequency and microwave radiation is a genotoxic carcinogen. Therefore it causes cellular mutations, and increased rates of cancer and Apoptosis in exposed populations, with no safe threshold level. This is backed up by a massive body of epidemiological studies.

At least 95 epidemiological studies have found increases in brain tumour in EMF/EMR exposed residents and workers, including military personnel exposed to radio and radar. Over 40 of them are statistically significant and there are over 50 dose-response relationships, and about half of them are significant. A similar number of occupational studies have found a statistically significant increase in leukaemia. In addition there are

many residential and occupational studies showing significantly increased adult and/or childhood leukaemia, over 20 with dose-response relationships and several with significant dose-response relationships. In addition there are several studies that report significant increases in "all cancer" from RF/MW exposure, some of these are also residential studies, and some have dose response relationships. This requires major reductions in the allowable public and occupational health protection exposure standards. Their levels should be set at such levels that chronic exposure do not result in detectable elevation of cancer, cardiac, reproductive and neurological health effects, once the ubiquitous exposures have been reduced.

Acute and chronic exposure levels of a genotoxic carcinogen has recommended be *de minimus*, that is, as small as possible. When there are those response relationships that point down towards zero, and existing levels very great deal, it is recommended that achievable safer guidelines are set and strategies developed and used to achieve it and get well below it.

The environmental performance indications of the desired levels can be decided by national or regional standards authorities. The New Zealand Ministry for the Environment promotes an approach set out in Table 25.

Table 25: Environmental Performance Indicators Programme air quality categories, Ministry for the Environment.

Category	Measured value	Comment
Action	Exceeds the guideline value	Exceedences of the guideline are a cause for concern and warrant action if they occur on a regular basis.
Alert	Between 66% and 100% of the guideline value	This is a warning level, which can lead to exceedences if trends are not curbed.
Acceptable	Between 33% and 66% of the guideline value	This is a broad category, where maximum values might be of concern in some sensitive locations, but are generally <i>at a</i> level that does not warrant dramatic action.
Good	Between 10% and 33% of the guideline value	Peak measurements in this range are unlikely to affect air quality.
Excellent	Less than 10% of the guideline value	Of little concern: if maximum values are less than a 10th of the guideline, average values are likely to be much less.

It is simply not scientifically credible to claim that there are no established non-thermal effects and hence it is wrong to adopt a guideline such as the ICNIRP guideline as a public exposure standard.

Where exposure levels are regularly above a practically achievable guideline or standard, for the disease agents whose safe level is actually zero, then a management plan should be developed to reduce exposures to have no exceedences of the desired target level. When the 0 exceedences level has been achieved then further reductions should be sought to progressively reduce the rates of the adverse health effects. Where the exposures are lower than the chosen target level then they should be maintained and where the community desires, be reduced towards the good (33%) or excellent level, 10% of the target standard.

For residential ELF exposures in the community a desirable and achievable standard level of

1mG (0.1μT),

with a good level of 0.33mG and an excellent level of 0.1mG.

For residential radio-frequency and microwave exposures in the community an initial desirable and achievable direct external standard level of

0.1μW/cm²

is recommended, as it is applied in Salzburg, Austria. Because their signals are genotoxic carcinogens there is no safe threshold and the exposures need to be minimized. An excellent level is 0.01μW/cm². With the large reduction of indoor exposures of less than 2% of the outdoor exposure, away from windows facing a source antenna, allowing for inside and outside, and home and away activity a mean level of 5% can be achieved, which for an excellent situation would result in a mean exposure of about 0.5nW/cm².
